ABSTRACT OF THE DISSERTATION

Pseoudoholomorphic quilts and Khovanov homology

by Reza Rezazadegan

Dissertation Director: Christopher Woodward

We generalize the symplectically-defined link homology theory developed by Paul Seidel and Ivan Smith to an invariant of tangles. We obtain a group-valued invariant, a functor-valued (or symplectic-valued functor) invariant and an $A_\infty$-functor-valued one for tangles. We provide evidence for the equivalence of this invariant with Khovanov’s combinatorially defined invariant by showing the equivalence for flat (crossingless) tangles and their cobordisms. We also obtain an exact triangle for the Seidel-Smith invariant similar to that of Khovanov.
Acknowledgements

In my time in graduate school I had the opportunity to get to know a variety of wonderful mathematicians. Among them Chris Woodward was a source of inspiration and challenge and was supportive in difficult times. I would also like to thank my friends in Rutgers in particular John McCabe, Sara Blight and Thotsaporn “Aek” Thanatipanonda. At last four years of graduate school and twenty two years of school in general is over. Have quilts, will travel.

Chapter 1
Introduction

1.1 Background

The topic of this thesis lies at the intersection of low dimensional topology, representation theory and symplectic geometry.

Symplectic geometry studies phase spaces originally arising from physical systems. However in modern mathematics one studies more abstract phase spaces which arise as the moduli spaces of geometric structures on low dimensional manifolds. Low dimensional topology studies spaces of dimensions two, three and four up to topological equivalence and the embeddings of curves and surfaces into such spaces. In low dimensional topology one is interested in finding invariants which can tell topologically different spaces apart. As an example, knots are embeddings of the circle into the three dimensional space and links are embeddings of a finite number of circles into this space. Knot theory was not considered to be a genuine part of mathematics at first but since its relations to other branches of mathematics started to be discovered in nineteen-eighties, it has been the subject of extensive research. The reason behind these relations is that knotting, linking and braiding occur in various areas of mathematics such as representation theory, symplectic geometry, algebraic geometry and that is why there are link invariants coming from all these branches.

Every link can be obtained as the closure of a braid and braids form a group. That is how knot theory is related to representation theory. The first such connection was discovered by V. Jones [12] where he studied the representations of braid group on Hecke algebras and obtained a polynomial knot invariant, the celebrated Jones polynomial. Jones’s work inspired a flurry of activity whose notable outcomes were Witten’s Chern-Simmons TQFT [41] and Reshetikhin-Turaev knot invariants [28]. The
latter one obtains a knot invariant from the representation theory of any quantum group. In this framework the Jones polynomial corresponds to quantum $\mathfrak{sl}_2(\mathbb{C})$.

The introduction of categorification into low dimensional topology was another turning point in the subject. Categorification is the process of replacing sets-theoretic structures with category-theoretic ones. A category of objects potentially has more structure than a set of elements because there are morphisms between its objects. In the year 2000 M. Khovanov [14] introduced a link invariant which assigns a doubly graded vector space to a given knot. This invariant categorifies the Jones polynomial in the sense that its graded Euler characteristic equals the Jones polynomial. It turns out that Khovanov homology has more structure than Jones polynomial and is able to tell some links apart which the Jones polynomial is not able to. Another work in this direction was knot Floer homology [26] which categorifies the Alexander polynomial of a knot and extends to an invariant of three and four manifolds.

The main difference between these two instances of categorification is that Khovanov homology is given purely combinatorially but Heegaard-Floer homology was originally defined using Lagrangian Floer homology. A combinatorial description of knot-Floer homology was obtained later [20]. This raises the question of whether there is a geometric model for Khovanov homology or in other words categorification of the Jones polynomial using differential geometry. In addition to the phenomenological aspect of this question, finding such a geometric picture would make computation of Khovanov homology for families of knots possible and would bring extension of this invariant to three and four manifolds within closer reach.

Symplectic geometry possesses powerful tools which can be used in categorification. Among these are Lagrangian Floer cohomology, Fukaya categories and Mau-Wehrheim-Woodward functor. Floer cohomology was one of the first indications of the algebraic structure behind symplectic geometry. To each pair of Lagrangian submanifolds $L, L'$ of a compact symplectic manifold, satisfying extra technical conditions, Floer cohomology assigns a graded abelian group $HF(L, L')$ whose Euler characteristic equals the intersection number of the two submanifolds. Therefore Floer cohomology categorifies
intersection number. Fukaya category $\text{Fuk}(M)$ of a symplectic manifold $M$ is an algebraic object which contains information about the Floer chain complex of each pair of Lagrangian submanifolds of $M$. To any Lagrangian submanifold $L$ of the product $M^{-} \times N$ of two symplectic manifolds, Mau, Wehrheim and Woodward [21] assign an $A_{\infty}$ functor $\Phi^{\#}_{L}$ from $\text{Fuk}(M)$ to $\text{Fuk}(N)$. This provides us with a tool for obtaining categorical invariants of manifolds as follows. Roughly speaking to each $d$-dimensional manifold $X$ one assigns a symplectic manifold $M(X)$ which is the moduli space of geometric structures of a specific type on $X$. For example to each Topological surface one can assign the moduli space of Flat connections on it. Then for any $(d + 1)$-dimensional cobordism $Y$ between $X_1$ and $X_2$ one obtains a Lagrangian submanifold $L_Y \subset M(X_1)^{-} \times M(X_2)$ which consists of pairs of structures on $X_1$ and $X_2$ which extend over to $Y$. Since every $d$-dimensional manifold can be decomposed into elementary pieces using Morse theory, this method assigns a sequence of Lagrangian submanifolds, a Lagrangian correspondence, to each such manifold. One can either compute the Floer cohomology of this correspondence or apply the Mau-Wehrheim-Woodward construction and obtain an $A_{\infty}$ functor.

An attempt at constructing a symplectic-geometric categorification of the Jones polynomial, or in other words a geometric model for Khovanov homology, was made by P. Seidel and I. Smith [35]. Their model gives a knot invariant using symplectic geometry which is conjecturally equivalent to Khovanov homology. The essential ingredient in their construction is a representation

$$h : Br_{m} \rightarrow \pi_{0}(\text{Symp}(\mathcal{Y}_{m}))$$

of the braid group into the symplectic mapping class group of certain algebraic varieties $\mathcal{Y}_{m}$. For a link $K$ given as the closure of a braid $\beta \in Br_{m}$, the Seidel-Smith invariant is the Floer cohomology

$$HF(L, h_{\beta}(L))$$

of $L$ and $h_{\beta}(L)$ where $L$ is a specific Lagrangian submanifold of $\mathcal{Y}_{m}$. They prove that this group is independent of the choice of the braid representation $\beta$. Later C. Manolescu [17] gave a more explicit description of the invariant and equipped the chain complex
with a second grading, showing that the Euler characteristic of this chain complex equals the Jones polynomial. However it is not known if this grading descends to a grading on cohomology. The representation (1.1) is in fact the monodromy representation of a fiber bundle

$$\chi : \mathcal{S}_m \to \text{Conf}_{2m}$$

over the configuration space with fiber $\mathcal{V}_m$. Here $\mathcal{S}_m$ is the transverse slice to the orbit under the adjoint action of a nilpotent matrix of the Jordan form $(m, m)$ in the Lie algebra $\mathfrak{sl}_{2m}(\mathbb{C})$. Here we can see a connection to the Lie groups $SL_n$. The number of blocks in the Jordan matrix whose adjoint orbit is used, is related to the fact that the invariant one obtains is expected to be related to the quantum $\mathfrak{sl}_2$ link invariant. Ciprian Manolescu used this analogy to obtain link invariants which are expected to be related to $\mathfrak{sl}_n$ link invariants [18]. They specialize to the Seidel-Smith invariant when $n = 2$. There is a program for generalizing this construction to all Reshetikhin-Turaev invariants. See below.

There are two main problems with the above constructions. Firstly while Khovanov homology and algebraic categorifications of $\mathfrak{sl}_n$ link polynomials are doubly graded, the symplectic categorifications have only one grading. The conjectural relation expects the symplectic invariants to equal their corresponding algebraic invariant after the collapse of the bigrading on the latter one. The second problem is that this equivalence has not been established. Roughly speaking the symplectic invariants might have higher differentials coming from higher pseudoholomorphic polygons which are not present in Khovanov homology.

### 1.2 Foreground

In this thesis we construct a generalization of the Seidel-Smith invariant to even tangles. Tangles are, roughly speaking, knots with endpoints and the invariant assigned to them has more algebraic structure. An $m$-braid is a function from the set of $m$ points to itself and Seidel and Smith assign a mapping to such a function. An $(m, n)$ tangle is a correspondence between a set of $m$ points and a set of $n$ points and what we assign
to it is a Lagrangian correspondence. To any elementary \((m,n)\)-tangle \(T\) we assign a Lagrangian correspondence \(L_T\) between \(\mathcal{Y}_m\) and \(\mathcal{Y}_n\). If \(T\) is a braid, we assign to it the graph of the symplectomorphism \(h_T\) defined by Seidel and Smith. The elementary tangles other than braids are caps and cups. To a \((m,m+2)\) cap we assign a vanishing cycle over the diagonal \(\Delta \subset \mathcal{Y}_m \times \mathcal{Y}_m\). The Lagrangian assigned to a cup is the transpose of this vanishing cycle. See section 5.1. Now any given \((m,n)\)-tangle \(T\) can be decomposed into a composition of elementary ones

\[ T = T_k T_{k-1} \cdots T_1. \]

To \(T\) we assign the \textit{generalized} Lagrangian correspondence

\[ \Phi(T) = (L_{T_k}, L_{T_{k-1}}, \cdots, L_{T_1}) \]

between \(\mathcal{Y}_m\) and \(\mathcal{Y}_n\). We then prove that up to isomorphism of generalized correspondences, \(\Phi(T)\) is independent of the decomposition of \(T\) into elementary tangles.

This way we obtain two invariants for each \((m,n)\)-tangle \(T\). The first one is a functor \(\Phi^\#_T\) from the generalized Fukaya category of \(\mathcal{Y}_m\) to that of \(\mathcal{Y}_n\). The category used here is an enlargement of the Fukaya category of a Stein manifold to include a special class of noncompact Lagrangians. The second one is a graded abelian group, denoted \(\mathcal{HSS}(T)\), which is, roughly, the Floer cohomology of \(\Phi(T)\). For this second invariant to be well-defined we first have to deal with the compactness of the involved moduli spaces. The reason is that the Lagrangians assigned to caps and cups are not compact. We prove compactness using standard (but not very well-known) arguments on Lagrangians in manifolds with contact type boundary. In sections 2.9 and 2.10 we put together necessary tools for construction of Floer homology of noncompact Lagrangians in Stein manifolds. From these and the Functoriality Theorem of [39] we get the following.

\textbf{Theorem 5.2.3.} \(\mathcal{HSS}(T)\) is well-defined and is independent of the decomposition of \(T\) into elementary tangles.
In Chapter 7 we provide further evidence for the equivalence of the two invariance. We prove that the two invariants are equal for flat tangles, we establish an exact triangle for the Seidel-Smith invariant and finally we construct a homomorphism from Seidel-Smith to Khovanov homology with flattened grading.

This work is of interest within symplectic geometry as well. The aforementioned conjecture would follow if one can endow the Fukaya category of the symplectic manifolds $\mathcal{Y}_m$ (which are Milnor fibers) with an extra piece of structure namely a second grading. A crucial property of the Fukaya category of these manifolds is that it is generated by finitely many elements. One can hope to obtain such a second grading by mimicking the construction of homological grading on Khovanov homology.

Joel Kamnitzer [13] has proposed a method for categorifying all link polynomials from quantum groups. In this picture, for a complex reductive group $G$, the symplectic fibration used by Seidel and Smith (which is in fact the adjoint quotient map) is replaced by a fibration whose total space is the Beilinson-Drinfeld Grassmannian. This Grassmannian is, roughly speaking, the moduli space of $G^\vee$-bundles on $\mathbb{P}^1$ which are trivial on the complement of a finite set of points. Here $G^\vee$ is the Langlands dual of $G$. When two such points approach each other, one has a similar situation to that of Seidel-Smith where two eigenvalues come together. Kamnitzer proves a local neighborhood theorem analogous to that of Seidel and Smith.

1.3 Organization of chapters

In Chapter 2 we review the fundamentals of Lagrangian Floer theory and its quilted version.

In Chapter 3 we review Khovanov’s invariant for tangles from [15] and [14].

In Chapter 4 we review the construction of Seidel’s and Smith’s Floer theoretic
link invariant from [35] and then in Chapter 5 we generalize this invariant to tangles.

In Chapter 6 we enhance the group-valued invariant of Chapter 4 into an $A_\infty$ functor valued invariant. In other words to each $(m, n)$-tangle we assign an $A_\infty$ functor between the Fukaya categories of the manifolds $Y_m$ and $Y_n$.

Finally in Chapter 7 we study the symplectic invariant further and provide new evidence for its equivalence with Khovanov invariant.
Chapter 2

Quilted Lagrangian Floer cohomology

In this chapter we review the definition of Lagrangian Floer cohomology from [3] and [23] and its quilted version from [38]. The book [22] is the standard reference for the case of closed curves. Let \( L_0, L_1 \) be two Lagrangian submanifolds of a symplectic manifold \( M \). If some extra conditions (to be discussed below) are satisfied by \( M \) and \( L_0, L_1 \) then Floer cohomology assigns an abelian group \( HF(L_0, L_1) \) to the pair \( L_0, L_1 \).

2.1 Lagrangian correspondences

**Definition 2.1.1.** A symplectic manifold \((M, \omega)\) consists of a differentiable manifold \( M \) together with a closed nondegenerate differential two-form \( \omega \) on \( M \). We denote \((M, -\omega)\) by \( M^- \).

Lagrangian submanifolds are the most important class of submanifolds of a symplectic manifold. They provide the right setting for studying boundary value problems in symplectic manifolds.

**Definition 2.1.2.** A Lagrangian submanifold of a symplectic manifold \((M^{2n}, \omega)\) is \( n \) dimensional submanifold of \( M \) such that the restriction of \( \omega \) to \( L \) is zero.

For example if \( \phi : (M, \omega) \rightarrow (N, \omega') \) is a symplectomorphism, i.e. if \( \phi^* \omega' = \omega \) then the graph of \( \phi \) is a Lagrangian submanifold of \( M^- \times N \). The notion of a symplectomorphism between two symplectic manifolds is a rather restrictive one. For example the two manifolds have to have the same dimension. Lagrangian correspondences provide a more flexible notion of correspondence between symplectic
Definition 2.1.3. A Lagrangian correspondence $L$ between two symplectic manifolds $M_0$ and $M_1$ is a Lagrangian submanifold of $M_0^{-} \times M_1$. The transpose $L^t$ of $L$ is defined to be the same set regarded as a Lagrangian submanifold of $M_1^{-} \times M_0$.

Just as symplectomorphisms, there is a notion of composition for Lagrangian correspondences. In fact there are two such notions.

Definition 2.1.4. If $L_{0,1}$ is a Lagrangian correspondence between $M_0, M_1$ and $L_{1,2}$ is a correspondence between $M_1, M_2$ then the geometric composition $L_{0,1} \circ L_{1,2}$ is defined as

$$L_{0,1} \circ L_{1,2} := \{(m,m'')| \exists m' \in M_1 \text{ s.t.} (m,m') \in L_{0,1}, (m',m'') \in L_{1,2}\}$$

which is a subset of $M_0 \times M_2$.

Definition 2.1.5. This composition is embedded if $L_{0,1} \times L_{1,2} \subset M_0 \times M_1 \times M_1 \times M_2$ intersects the diagonal $M_0 \times \Delta_{M_1} \times M_2$ transversely and the projection $\pi_{0,2} = \pi_0 \times \pi_2$ embeds the intersection into $M_0 \times M_2$. In this case the composition is a Lagrangian submanifold of $M_0^{-} \times M_2$. Here $\pi_i$ is the projection onto $M_i$.

Since both $L_{0,1} \times L_{1,2}$ and $M_0 \times \Delta_{M_1} \times M_2$ are Lagrangian submanifolds of $M_0^{-} \times M_1 \times M_1^{-} \times M_2$, the composition $L_{0,1} \circ L_{1,2}$ is a Lagrangian submanifold of $M_0^{-} \times M_2$ if it is embedded. In order to remedy the problem of Lagrangian correspondences whose composition is not embedded, Wehrheim and Woodward [39] introduced the notion of generalized Lagrangian correspondence.

Definition 2.1.6. A generalized Lagrangian correspondence between symplectic manifolds $M, M'$ consists of a sequence $M = M_0, M_1, \ldots, M_n = M'$ of symplectic manifolds and a sequence $\mathcal{L} = (L_{0,1}, \ldots L_{i,i+1}, \ldots L_{n-1,n})$ such that $L_{i,i+1}$ is a Lagrangian correspondence between $M_i$ and $M_{i+1}$. In case $M' = pt$, we call $\mathcal{L}$ a generalized Lagrangian submanifold of $M$. We call $\mathcal{L}$ compact if each $L_{i,i+1}$ is compact.
There is an alternative notion of composition for Lagrangian correspondences.

**Definition 2.1.7.** The algebraic composition $L \# L'$ of two generalized Lagrangian correspondences $L = (L_k, L_{k-1}, \ldots, L_1)$ from $M_0$ to $M_1$ and $L' = (L'_l, L'_{l-1}, \ldots, L'1)$ from $N_1$ to $N_2$ is the correspondence $(L_k, L_{k-1}, \ldots, L_1, L'_l, L'_{l-1}, \ldots, L'1)$ from $M_0$ to $M_2$.

According to [39] Section 2.2, the *symplectic category* is the category whose objects are monotone symplectic manifolds (including exact ones) and whose morphisms are equivalence classes of generalized Lagrangian correspondences. The equivalence relation on morphisms is generated by the following two relations. Firstly,

$$(L_0, L_{0,1}, \ldots, L_{i,i+1}, \ldots, L_{n-1,n}, L_n)$$

is equivalent to

$$(L'_0, L'_{0,1}, \ldots, L'_{i,i+1}, \ldots, L'_{n-1,n}, L'_n)$$

if each $L_{i,i+1}$ is Hamiltonian isotopic to $L'_{i,i+1}$ in $M_i^- \times M_{i+1}$. Secondly

$$(L_0, L_{0,1}, \ldots, L_{i-1,i}, L_{i,i+1}, \ldots, L_n)$$

is equivalent to

$$(L_0, L_{0,1}, \ldots, L_{i-1,i} \circ L_{i,i+1}, \ldots, L_n)$$

whenever the composition $L_{i-1,i} \circ L_{i,i+1}$ is embedded. The idea of symplectic category goes back to Weinstein [40] where he considered only Lagrangian correspondences as morphisms. Since the composition of two Lagrangian correspondences might not be embedded, he did not obtain a genuine category.

**Definition 2.1.8.** A $d+1$ dimensional symplectic valued topological field theory is a functor from the category ($d$-manifolds, cobordisms) to the symplectic category. Here “cobordism” means cobordism modulo isotopy. A genus zero symplectic valued topological field theory is a functor from the category of $d-2$ dimensional submanifolds of $\mathbb{R}^d$ with boundary and cobordisms between them to the symplectic category.
2.2 Maslov Index

Let $\mathcal{L}(n)$ be the set of all Lagrangian subspaces of $\mathbb{C}^n$. We have $\mathcal{L}(n) \cong U(n)/O(n)$.

**Definition 2.2.1.** If $\gamma : S^1 \to \mathcal{L}(n)$ is a loop define its Maslov index to be

$$\mu(\gamma) = \deg(\det^2 \circ \gamma).$$

One can assign a Maslov index to a pair of paths of Lagrangian subspaces as follows. This definition is due to Robbin and Salamon [30]. Let $\Lambda$ be a path of Lagrangians in $\mathbb{C}^n$ such that

$$\Lambda(t) = \text{image } Z(t) = \begin{pmatrix} X(t) \\ Y(t) \end{pmatrix} : \mathbb{R}^n \to \mathbb{C}^n.$$  

To $\Lambda$ we associate the quadratic form given by

$$Q_{t_0}(\Lambda)(v) = \langle X(t_0)u, \dot{Y}(t_0)u \rangle - \langle Y(t_0)u, \dot{X}(t_0)u \rangle$$  (2.1)

for $v = Z(t)u$. Let $\Lambda'$ be another path of Lagrangians in $\mathbb{C}^n$ such that

$$\Lambda'(t) = \text{image } Z'(t) = \begin{pmatrix} X'(t) \\ Y'(t) \end{pmatrix} : \mathbb{R}^n \to \mathbb{C}^n.$$  

**Definition 2.2.2.** A crossing is a $t_0$ such that $\dim \Lambda(t_0) \cap \Lambda'(t_0) > 0$. The relative crossing form of such a crossing $t_0$ is defined to be

$$\Gamma_{t_0}(\Lambda, \Lambda') := Q_{t_0}(\Lambda)|_{\Lambda'(t_0) \cap \Lambda(t_0)} - Q_{t_0}(\Lambda')|_{\Lambda(t_0) \cap \Lambda'(t_0)}.$$  (2.2)

**Definition 2.2.3.** The Maslov index of the pair $\Lambda, \Lambda'$ is defined to be

$$\mu(\Lambda, \Lambda') = \frac{1}{2} \text{sign } \Gamma_{-\infty}(\Lambda, \Lambda') + \frac{1}{2} \text{sign } \Gamma_{+\infty}(\Lambda, \Lambda') + \sum_{t \text{crossing}} \text{sign } \Gamma_t(\Lambda', \Lambda).$$  (2.3)

Let $E$ be a trivial $\mathbb{C}^n$ bundle over the strip $\mathbb{D} = [0, 1] \times \mathbb{R}$. Let $F$ be a subbundle of $E|_{\partial \mathbb{D}}$ with Lagrangian fibres. For any choice of trivialization $\Phi$ of $E$ we get two maps $\gamma_0, \gamma_1 : \mathbb{R} \to \mathcal{L}(n)$ defined by $\gamma_i(t) = \Phi(F_{(t, i)})$.

**Definition 2.2.4.** Define the Maslov index of $(E, F)$ to be

$$\mu(E, F) = \mu(\gamma_1, \gamma_2).$$  (2.4)
2.3 Pseudoholomorphic polygons

Recall that an almost complex structure on a manifold $M$ is a field of endomorphisms of the tangent bundle of $M$, $J \in \Gamma(\text{End}(TM))$, such that $J \circ J = -\text{id}$. Let $(M, \omega)$ be a symplectic manifold.

**Definition 2.3.1.** An almost complex structure $J$ on $M$ is compatible with $\omega$ if and $\omega(\cdot, J\cdot)$ is a Riemannian metric on $M$.

**Definition 2.3.2.** A surface with strip like ends $(S, \mathcal{E}^+, \mathcal{E}^-)$ consists of

- a Riemann surface $S$ together with two sets $\mathcal{E}^+, \mathcal{E}^- \subset \partial \bar{S}\setminus S$ called outgoing and incoming ends
- for each outgoing end $\zeta \in \mathcal{E}^+$ a biholomorphic map
  \[
  \iota_\zeta : [0, 1] \times \mathbb{R}^+ \to S
  \]
  and for each incoming end $\zeta \in \mathcal{E}^-$ a biholomorphic map
  \[
  \iota_\zeta : [0, 1] \times \mathbb{R}^- \to S
  \]
  such that $\iota_\zeta^+$(resp. $\iota_\zeta^-$) maps the boundary of $[0, 1] \times (0, \infty)$ to $\partial S$ and
  \[
  \lim_{t \to +\infty} \iota_\zeta(s, t) = \zeta
  \]
  (resp. $\lim_{t \to -\infty} \iota_\zeta(s, t) = \zeta$). We assume that endpoints on each boundary component of $S$ are ordered cyclically so for each endpoint $\zeta$ we have boundary components $c_+ (\zeta)$ and $c_- (\zeta)$. We also assume that $\mathcal{E}^+(S) \cup \mathcal{E}^-(S) = \bar{S}\setminus S$.

Given such a surface, a family of almost complex structures parameterized by $S$ is a map $J$ that assigns a $C^\infty$ almost complex structure $J(x)$ on $M$ compatible with $\omega$ to each point $x \in S$ such that

\[
(t_\zeta^* J)(s, t) = J_\zeta(t)
\]

(2.5)

does not depend on $s$. Let $c_1, \ldots, c_m$ be the boundary components of $S$ and let $L_1, \ldots, L_m$ be Lagrangian submanifolds of $M$. 
**Definition 2.3.3.** A $J$-holomorphic $m$-gon with boundary condition $L_1, \ldots, L_m$ is a map $u \in W^{1,p}(S, M)$, for some fixed $p > 2$, satisfying

1. $J(u(x)) \circ du(x) = du(x) \circ j$ for all $x \in S$
2. $u(c_i) \subset L_i$, for $i = 1, \ldots, m$.

The case $m = 2$ is of special importance. Let $\mathbb{D}$ denote the strip $[0, 1] \times \mathbb{R}$. The equation (2.5) translates into the fact that $J = J(t)$ is a path of $C^\infty$ almost complex structures on $M$ compatible with $\omega$. Denote by $J$ the set of all such paths on $M$. The equation $U1$ translates into

$$\partial_su(s, t) + J(t)(u(s, t)) \partial_t u(s, t) = 0.$$ 

Let $L_1, L_2$ be two lagrangian submanifolds of $M$. We assume $L_1$ and $L_2$ intersect transversely. If both Lagrangians are compact then there is a Hamiltonian symplectomorphism of $M$ which makes $L_1$ and $L_2$ transverse to each other. Let $x, y \in L_1 \cap L_2$. A $J$-holomorphic strip joining $x$ and $y$ is a map $u : \mathbb{D} \to M$ satisfying $U1$ and $U2$ as well as

3. $\lim_{t \to \infty} u(s, t) = y$, $\lim_{t \to -\infty} u(s, t) = x$.

Each such $u$ induces a map $v : \mathbb{D}^2 \to M$ which is $J$-holomorphic on the interior of $\mathbb{D}^2$ and $v(\sqrt{-1}) = y$, $v(-\sqrt{-1}) = x$. Let $\mathcal{M}(x, y, J)$ denote the set of all such $J$-holomorphic strips. It inherits a topology as a subset of $W^{1,p}(S, M)$. To each such $u$ one can assign a Maslov index (See Section 2.2)

$$\mu(u) = \mu(u^*TM, F)$$

where $F$ is given by the pullback of $TL_1$ and $TL_2$ to $\partial\mathbb{D}$. Let $\mathcal{M}_k(x, y, J)$ denote the subset of $\mathcal{M}(x, y, J)$ containing elements of Maslov index $k$.

**Definition 2.3.4.** The area of $u$ is

$$A(u) = \int_{\mathbb{D}} u^*\omega.$$
The energy of $u$ is
\[ E(u) = \int_{\mathbb{D}} \|du\|^2 \]
where the norm is given by the metric $\omega(\cdot, J \cdot)$.

### 2.4 Gromov Compactness

Let $J$ be of class $C^\infty$ and let \{${u_n}$\} be a sequence in $\mathcal{M}(x, y, J)$ with bounded area. As before we denote the (pointwise) norm of the one form $du$ in the metric $\omega(\cdot, J \cdot)$ by $\|du\|$. If $\|du_n\|$, as a function on $\mathbb{D}$, is uniformly bounded it follows from elliptic bootstrapping that a subsequence of $u_n$ converges (in $C^\infty$ topology) on compact subset of $\mathbb{D}$ to a $J$-holomorphic map (See e.g. Theorem B.4.2 in [22]).

In general one just has a bound on the energy of the curves and so $\|du_n\|$ might not be uniformly bounded at all points. This results in the bubbling phenomenon.

**Definition 2.4.1.** Call a point $z_0 \in \mathbb{D}$ singular if there is a sequence of points $z_n \to z_0$ such that $\|du_n(z_n)\| \to \infty$.

Let $S_1$ (resp. $S_2$) be the set of singular points on the interior (resp. boundary) of $\mathbb{D}$. If $z_0 \in S_1$ (resp. $S_2$) define
\[ v_n(z) = u_n(z_n - z/c_n) \quad (2.7) \]
on a neighborhood $B_r(0)$ in $\mathbb{C}$ (resp. $\mathbb{H}$). We have $\|dv_n(z)\| = \|du_n(z_n - z/c_n)/c_n\|$ so with an appropriate choice of $c_n$, $v_n$ has uniformly bounded derivative on $B_r(0)$ so converges to a curve $v : B_r(0)$ (resp. $B_r(0) \cap \mathbb{H}$) $\mapsto M$. It follows from the invariance of area that $v(1/z)$ has finite area so by removal of singularities theorem its singularity at 0 is removable so $v$ is defined on whole of $S^2$ (resp. $\mathbb{D}$).

It can be seen that
\[ E(v) = \lim_{\epsilon \to 0} \lim_{n \to 0} \int_{B_r(z_0)} v_n^* \omega. \quad (2.8) \]
We denote this quantity by $E(z_0)$.

If $S = S_1 \cup S_2$ denotes the set of all singular points for $u_n$ then $\|du_n\|$ is uniformly bounded on $\mathbb{D} \setminus S$ so a subsequence of $u_n$ converges in $C^\infty$ topology
to a holomorphic curve $u : D \setminus S \to M$ on compact subsets of $D \setminus S$. We have $E(u_n) = \int_{D \setminus B_r(S)} u_n^*\omega + \int_{B_r(S)} u_n^*\omega$ so

$$\lim E(u_n) = E(u) + \sum_{z \in S} E(z).$$

Since there is a $\hbar > 0$ such that each holomorphic sphere in $M$ has energy greater than or equal to $\hbar$ ([22], Proposition 4.14), $S$ is a finite set. The limit map can be thought of as a set of maps $(u, v_1, \ldots, v_k)$ where $k = \#S$ and $u : D \setminus S \to M$, $v_i : S^2 \to M$ are $J$-holomorphic. The maps $v_i$ are the rescaled maps (2.7).

There is another phenomenon arising, from noncompactness of $D$, called broken flow lines.

**Theorem 2.4.2 ([4]).** If $\{u_n\}$ is a sequence of elements of $\mathcal{M}(x, y, J)$ of bounded energy then there are

- a finite number of points $x_1, \ldots, x_{l-1} \in L_0 \cap L_1$,
- a finite subset $S = \{z_1, \ldots, z_k\}$ of singular points in $D$,
- sequences $\{t_{n}^\alpha\}$ for $\alpha = 1 \ldots l$

such that $u^n(s, t) := u(s, t + t_n^\alpha)$ converges (in $C^\infty$ topology), on any subset of $D$ of the form $K \setminus \{z_1, \ldots, z_k\}$ with $K$ compact, to an element of $\mathcal{M}(x_{\alpha-1}, x_\alpha, J)$ where $x_0 = x, x_l = y$.

The maps $u^n$ are called broken flow lines. Using a gluing argument (as in Chapter 10 of [22]) one can show that for any broken flow line or strip with bubbles there is a sequence of the elements of $\mathcal{M}(x, y, J)$ converging to that curve in the sense of the Lemma 2.4.2 above. Therefore one can compactify the topological space $\mathcal{M}(x, y)$ by adding such limit curves.

### 2.5 Transversality

This section is devoted to the proof of the following theorem.
Theorem 2.5.1. There is a subset $\mathcal{J}_{\text{reg}}$ of second category in $\mathcal{J}$ such that $M_k(x, y, J)$ is a (noncompact) smooth manifold of dimension $k$ for $J \in \mathcal{J}_{\text{reg}}$

Let $\mathcal{B}$ denote the set of all $u \in C^\infty(\mathbb{D}, M)$ such that $u$ satisfies $\mathbf{U2}$ and $\mathbf{U3}$. Let $\mathcal{B}^{k,p}$ be the set of all $u \in W^{k,p}(\mathbb{D}, M)$ satisfying $\mathbf{U2}$ and $\mathbf{U3}$. The tangent space to $\mathcal{B}$ at $u$ is $T_u \mathcal{B} = \Omega^0(\mathbb{D}, u^*TM)$. Let $\mathcal{J}^l$ be the set of all paths of almost complex structures of class $C^l$ on $M$. The tangent space $T_J \mathcal{J}^l$ to $\mathcal{J}^l$ at a point $J$ can be identified with the set of all paths $Y : [0, 1] \to C^l(\text{End} TM)$ satisfying the following two conditions:

$$\omega(Yu, v) + \omega(u, Yv) = 0$$

and

$$Y(t)J(0) + J(t)Y(t) = 0$$

for all $t \in [0, 1]$. The set $\mathcal{J}^l$ has the structure of a Banach manifold with a chart at a point $J$ is given by $Y \to J \exp(-JY)$.

Let $g_J(u, v) = \frac{1}{2}(\omega(u, Jv) + \omega(v, Ju))$ and $\nabla$ be its Levi-Civita derivative. The modified derivative $\tilde{\nabla}_vX = \nabla_vX - \frac{1}{2}J(\nabla_vJ)X$ is $J$-linear. If $u \in \mathcal{B}$ and $\xi$ is a section of $u^*TM$ define

$$\Phi(\xi) : u^*TM \mapsto \exp_u(\xi)^*TM$$

to be the parallel transport along geodesics $\gamma(s) = \exp_{u(z)}(\xi(z))$. Set

$$\mathcal{F}_u(\xi) = \Phi_u^{-1}(\xi) \bar{\partial} \exp_u(\xi)$$

and define

$$D_u : \Omega^0(\mathbb{D}, u^*TM) \mapsto \Omega^{0,1}(\mathbb{D}, u^*TM)$$

by $D_u\xi = d\mathcal{F}(0)\xi$. Define $\mathcal{J}^l_{\text{reg}}$ to be the set of all $J$ of class $C^l$ such that for every $J$-holomorphic strip $u$, the operator $D_u$ is surjective and denote by $\mathcal{J}_{\text{reg}}$ the intersection of all these sets. An application of the inverse function theorem shows that for $J \in \mathcal{J}_{\text{reg}}$, $\mathcal{M}(x, y, J)$ is a finite dimensional manifold. Define

$$\mathcal{M}(x, y; \mathcal{J}^l) = \{(u, J) \in \mathcal{B}^{k,p} \times \mathcal{J}^l | u \in \mathcal{M}(x, y; J)\}.$$
We use the following facts in the proof of 2.5.1.

**Theorem 2.5.2** (Oh [24], Floer-Hofer-Salamon [5]). *Let \( u \in \mathcal{M}(x, y) \) then the set \( \Theta_u \) consisting of all \((s, t) \in \mathbb{D}\) for which*

- \( u(\{s\} \times [0, 1]) \) intersects \( u(\mathbb{R}\setminus\{s\} \times [0, 1])\),
- \( u(\{s\} \times [0, 1]) \cap (L_0 \cap L_1) = \emptyset \) and
- \( \frac{\partial u}{\partial s}(s, t) \neq 0 \) for all \( t \in [0, 1] \)

*is open and nonempty in \( \mathbb{D} \).*

**Theorem 2.5.3.** *(Unique Continuation)* *If \( u_1, u_2 : B_\epsilon(0) \rightarrow \mathbb{C}^n \) satisfy \( \partial_t u_i + J\partial_s u_i = 0 \) where \( J \) is an almost complex structure and \( u_1 - u_2 \) vanishes to infinite order at \( 0 \) then \( u_1 = u_2 \) on \( B_\epsilon \).*

*Proof.* Consider the bundle \( E \) on \( B^{k,p} \times \mathcal{J}^l \) whose fiber at \((u, J)\) equals

\[
L^p(\Omega^{0,1})(\mathbb{D}, u^* TM)
\]

and the section \( \mathcal{F}(u, J) = \bar{\partial}_J u \) of \( E \). We have to show that the differential of this section given by

\[
D\mathcal{F}(u, J)(\xi, Y) = D_u \xi + \frac{1}{2} Y(u) \circ du \circ j
\]

is injective at points of the intersection of the \( \mathcal{F} \) with the zero section i.e. at points \((u, J)\) where \( \mathcal{F}(u, J) = 0 \). Because \( D_u \) is Fredholm, it is sufficient to show that the image of \( D\mathcal{F} \) is dense whenever \( \mathcal{F}(u, J) = 0 \). If this is not true then by Hahn-Banach theorem there is a nonzero \( L^q \) section \( \eta \) of \( \Omega^{0,1}(\mathbb{D}, u^* TM) \) such that

\[
\int_{\mathbb{D}} < \eta, D_u \xi >= 0
\]

and

\[
\int_{\mathbb{D}} < \eta, Y \circ du \circ j >= 0
\]
for any $\xi$ and $Y$ so $D_u^*\xi = 0$. We show that $\eta(z_0) = 0$ for any $z_0 = (s_0, t_0) \in \Theta_u$ so by unique continuation theorem 2.5.3, $\eta$ is identically zero. If this is not true then because $du \neq 0$ there is $Y_0(t)$ such that $\langle \eta(z_0), Y_0(t_0) \circ du(z_0) \circ j \rangle > 0$. There is no other $t \in [0, 1]$ such that $u(s_0, t_0) = u(s_0, t)$ so the inverse image $u^{-1}(J_0(z_0))$ consists of finitely many points $\{z_0 = (s_0, t_0), z_1, ..., z_k = (s_0, t_k)\}$ where the $s_i$ are distinct. Let $\rho$ be a bump function on $[0, 1]$ concentrated in a small neighborhood $V$ of $t_0$. Then $\int_D < \eta, \rho Y_0 \circ du(z_0) \circ j > > 0$ which is contradiction.

Lemma 2.5.4. If $\pi : M(x, y; J^l) \to J^l$ is the projection on the second factor and $(u, J) \in M(x, y; J^l)$ then $\ker Du = \ker d\pi(u, J)$ and so $J^l_{\text{reg}}$ consists of regular values of $\pi$.

Proof. The tangent space to $M(x, y; J^l)$ at $(u, J)$ consists of $(\xi, Y)$ such that $D_u \xi + \frac{1}{2} Y(u) \circ du \circ j = 0$ and $d\pi(u, J)(\xi, Y) = Y$.

Corollary 2.5.5. For $l$ large enough, $J^l_{\text{reg}}$ is of second category in $J^l$.

Proposition 2.5.6. If $p > 2$ then $M(x, y; J^l)$ is a separable Banach submanifold of $B^{k,p} \times J^l$.

Taubes’ argument We now generalize the corollary 2.5.5 to the $C^\infty$ case. Define $J_{\text{reg}, k}$ to be set of all paths of almost complex structures $J$ such that if $u$ is any $J$-holomorphic strip with $\|du\|_{L^\infty} \leq k$ then $D_u$ is onto. We have $J_{\text{reg}} = \bigcap_{k>0} J_{\text{reg}, k}$. We will show that $J_{\text{reg}, k}$ is open and dense in $J$ for any $k$ so $J_{\text{reg}}$ is of second category in $J$. First note that $J_{\text{reg}, k}$ is open in $J$ for if $J_n$ is a sequence in the complement of $J_{\text{reg}, k}$ then there is a sequence of $J_n$-holomorphic curves $u_n$ such that $\|du_n\| \leq k$ and $D_{u_n}$ is not onto. Now a subsequence of $u_n$ converges to a $J$-holomorphic curve $u$ where $J$ is the limit of (a subsequence of) $J_n$. The map $u$ satisfies $\|du\| \leq k$ and $D_u$ which is the limit of $D_{u_n}$ is not surjective.
Now we prove that $J_{\text{reg},k}$ is dense in $J$. Let $J \in J$ by corollary 3.3 there is a sequence $J^l \in J_{\text{reg}}^l = \bigcap_{k' > 0} J_{\text{reg},k'}^l$ such that $\|J - J^l\|_{C^l} < 2^{-l}$ for $l$ large enough. Now because $J_{\text{reg},k}^l$ is open in $C^l$ topology, there is a $r_l$ such that if $\|J^l - J_l\|_{C^l} < r_l$ then $J^l \in J_{\text{reg},k}^l$. Choose $J^l$ to be $C^\infty$. So $\|J^l - J_l\|_{C^l} < \min\{r_l, 2^{-l}\}$ and $J^l \in J \cap J_{\text{reg},k}^l = J_{\text{reg},k}^l$.

### 2.6 Orientation of the moduli spaces

If the Lagrangians $L_0, L_1$ have some extra structure one can equip the manifolds $\mathcal{M}(x, y)$ with an orientation.

**Definition 2.6.1.** A spin structure on an orientable manifold $L^n$ is a principal $\text{Spin}(n)$ bundle $\tilde{P}$ and a two-fold covering map $\pi : \tilde{P} \to P$ where $P$ is the principal $\text{SO}(n)$ bundle associated to $TM$. The map $\pi$ is required to fit into the following commutative diagram.

$$
\begin{array}{ccc}
\text{Spin}(n) & \longrightarrow & \tilde{P} \\
\downarrow & & \downarrow \\
\text{SO}(n) & \longrightarrow & P
\end{array}
$$

A manifold admitting a spin structure is called a spin manifold.

For an orientable manifold $L$ to be spin it is necessary and sufficient that the second Stiefel-Whitney class of $L$ vanish. In particular if $L$ admits an almost complex structure whose first Chern class vanishes

**Theorem 2.6.2 ([7],[34]).** If Lagrangians $L_0, L_1$ are spin then the manifolds $\mathcal{M}(x, y)$ are orientable. Moreover each pair of spin structures on $L_0, L_1$ induces an orientation on the moduli spaces in a canonical way.

This theorem is also valid in the case of $k$ Lagrangians and the moduli space of pseudoholomorphic $k$-gons with boundary on the Lagrangians (Section 11 in [34]).
2.7 Definition of Lagrangian Floer cohomology

There is an action of \( \mathbb{R} \) on \( \mathcal{M}_k(x, y, J) \) given by \( u(s, t) \rightarrow u(s, t + \tau) \). The action is free for \( k > 0 \). This follows from unique continuation 2.5.3. Define

\[
\tilde{\mathcal{M}}_1(x, y, J) = \mathcal{M}_1(x, y, J)/\mathbb{R}.
\]

We impose the following two assumptions on \( L_0, L_1 \).

**L1)** Monotonicity: there exists a \( c > 0 \) such that for any smooth disc \( u \) with boundary on \( L_i \),

\[
\mu(u) = c \cdot A(u)
\]

where \( A(u) = \int_D u^* \omega \) is the area of \( u \) and \( \mu \) is its Maslov index.

**L2)** The image of \( \pi_1(L_0) \) in \( \pi_1(M) \) is torsion.

**Lemma 2.7.1.** Under the assumptions **L1** and **L2** all elements of \( \mathcal{M}_k(x, y, J) \) (for \( k \) fixed) have the same energy.

Proof. If \( u_1, u_2 \in \mathcal{M}_k(x, y, J) \) then \( \gamma = u_1(0, .) * u_2(0, .) \in \pi_1(L_0) \). It follows from **L2** there is a disc \( D \) in \( M \) and a number \( l \) such that \( \gamma^l = \partial D \). Now \( D \) together with \( u_1 \) and \( u_2 \) gives a disc \( v \) with boundary on \( L_1 \). By **L1** we have

\[
\mu(v) = cE(v) = c(E(u_1) - E(u_2) + lE(D))
\]

but \( \mu(v) = \mu(u_1) - \mu(u_2) + k\mu(D) = k - k + lcE(D) \). So \( E(u_1) = E(u_2) \). \( \square \)

**Corollary 2.7.2.** \( \tilde{\mathcal{M}}_1(x, y, J) \) consists of finitely many points.

Proof. If \( \{u_n\}_{n=1}^\infty \) is a sequence in \( \tilde{\mathcal{M}}_1(x, y, J) \) then by Gromov compactness, \( u_n \) converges to another element of \( \tilde{\mathcal{M}}_1(x, y, J) \) because, by monotonicity, a broken flow line has Maslov index \( \geq 2 \) and so does a sphere bubbling off. No discs could bubble off because by 2.7.1, elements of \( \tilde{\mathcal{M}}_1(x, y, J) \) have minimal energy and the energy is additive. So \( \tilde{\mathcal{M}}_1(x, y, J) \) is compact zero dimensional and hence finite. \( \square \)
Set $CF(L_0, L_1) = \mathbb{Z}/2\mathbb{Z} < L_0 \cap L_1 >$. If $L_0$ and $L_1$ satisfy the assumptions of Theorem 2.6.2 we set

$$CF(L_0, L_1) = \mathbb{Z} < L_0 \cap L_1 >.$$ 

Define $\partial^J : CF(L_0, L_1) \rightarrow CF(L_0, L_1)$ by

$$\partial^J x = \sum_{y \in L_0 \cap L_1} \# \tilde{M}_1(x, y, J)y.$$

In the $\mathbb{Z}/2\mathbb{Z}$ case the count is mod 2. In the oriented case $\tilde{M}_1(x, y, J)$ is oriented and zero-dimensional and the count is the sum of the signs of its elements.

**Theorem 2.7.3.** If $L_1, L_2$ satisfy $L1$ and $L2$ and in addition the minimal Maslov number of $L_1$ and $L_2$ is greater than or equal to 3 then $\partial^J \circ \partial^J = 0$.

In such a case we define $HF(L_1, L_2, J) = \ker \partial^J / \text{im} \partial^J$.

**Proof.** We have

$$< \partial \partial x, z > = \sum_{y \in L_0 \cap L_1} \# \tilde{M}_1(x, y, J) \cdot \# \tilde{M}_1(y, z, J).$$

By Gromov compactness $\tilde{M}_2(x, z, J)$ could be compactified to a manifold

$$\bar{M}_2(x, z, J)$$

such that $\partial \bar{M}_2(x, z, J)$ consists of broken flow lines or discs bubbling off. If minimal Maslov number is $\geq 3$, it could be shown no discs could bubble off: The case $x \neq z$ follows from monotonicity and additivity of the Maslov index. If $x = z$ then in the limit we might obtain a constant strip at $x$ and a disc with boundary on $L_0$ or $L_1$ through $x$. The dimension of the set of all such discs is the minimal Maslov number of $L_i$ ($\geq 3$) minus the dimension of the group of automorphisms of disc which fix a given point (which is two). So this dimension is greater than or equal to 1 hence this set could not be in the boundary of $\tilde{M}_2(x, z, J)$. So $\partial \bar{M}_2(x, z, J) \subset \bigcup_{y \in L_0 \cap L_1} \bar{M}_1(x, y, J) \times \bar{M}_1(y, z, J)$. A gluing argument establishes the reverse inclusion. $\square$
Independence of \( J \) could be shown by constructing chain maps \( \phi_{J,J'} \) and \( \phi_{J',J} \) from \( CF(L_0, L_1) \) to itself. See Theorem 3.6 in [31] for the closely related case of Floer homology for Hamiltonian fixed points.

2.8 Grading

The topic of this subsection is the absolute grading of Floer cohomology groups. We discuss the special case which is of concern in this thesis, i.e. the case of \( \mathbb{Z} \) grading. The reader is referred to [32] for more detail. Let \((M^{2n}, \omega)\) be a symplectic manifold. We know that for a Lie group \( G \) and its maximal compact subgroup \( K \), the isomorphism classes of \( G \) bundles on a topological space \( X \) are in one-to-one correspondence with those of \( K \) bundles over \( X \). The symplectic group \( Sp(2n) \) has \( U(n) \) as maximal compact subgroup therefore upon choosing a compatible almost complex structure the structure group of \( TM \) can be reduced to \( U(n) \). Denote by \( P \) the principal \( U(n) \) bundle we get from \( TM \) in this way.

**Definition 2.8.1.** An infinite Maslov cover of \( M \) is a \( SU(n) \) bundle \( \tilde{P} \) over \( M \) such that \( \tilde{P} \times_{SU(n)} \mathbb{C}^n = TM. \)

Since the universal cover \( \tilde{U(n)} \) of \( U(n) \) has \( SU(n) \) as maximal compact subgroup, we get an equivalent definition by replacing \( SU(n) \) with \( \tilde{U(n)} \) in the above definition.

**Lemma 2.8.2.** If the structure group of \( TM \) can be further reduced to \( SU(n) \) then \( M \) has an infinite Maslov covering.

**Proof.** Let \( g_{\alpha,\beta} \) and \( g'_{\alpha,\beta} \) be transition functions of \( TM \) as a \( U(n) \) resp. \( SU(n) \) bundle over the same covering of \( M \). Then the transition functions \( \{(g_{\alpha,\beta}, t) \mid g_{\alpha,\beta} = e^{it}g'_{\alpha,\beta}\} \) define a \( \tilde{U(n)} \) bundle \( \tilde{P} \) over \( M \) for which we have \( \tilde{P} \times_{\tilde{U(n)}} \mathbb{C}^n = TM. \)

The isomorphism classes of such covers are in one to one correspondence with \( H_1(M) \). Let \( \mathcal{L} \to M \) be the bundle whose fiber at \( x \in M \) is the Lagrangian
Grassmanian of $T_xM$. A Maslov cover $\tilde{P}$, induces a covering $\tilde{L} \to L$ given by $\tilde{P} \times_{SU(n)} \tilde{\text{Lag}}(n)$. Each Lagrangian submanifold $L$ of $M$ determines a section $s_L$ of $\mathcal{L}$. A grading of $L$ is a cover $\tilde{s}_L$ of $s_L$. If $L_0, L_1$ are two Lagrangian submanifolds of $M$ that intersect transversely we can assign an absolute grading to each intersection point $x$ as follows. Let $\tilde{\Lambda}_i = \tilde{s}_{L_i}$ for $i = 0, 1$. Let $\tilde{\Lambda}(t)$ be a path joining $\tilde{\Lambda}_0$ to $\tilde{\Lambda}_1$ and let $\Lambda(t)$ be its projection. Define

$$\deg(x) = \mu^\text{path}(\Lambda, T_xL_0) + \frac{n}{2}$$

(2.9)

where $\mu^\text{path}$ is the Maslov index for paths. It does not depend on the choice of the liftings $\tilde{s}_{L_i}$ because of the naturality of $\mu^\text{path}$. In general if the canonical bundle is not trivial, one can obtain only a $\mathbb{Z}/N$ grading for some $N \in \mathbb{N}$.

There is an equivalent way of describing this grading. If the canonical bundle of $M$ is trivial, it has a global section (or trivialization) $\eta$. The global section $\eta$ gives us a map $\alpha_M : M \to S^1$ given by

$$\alpha_M(x) = \frac{\eta(u_1, \ldots, u_n)^2}{|\eta(u_1, \ldots, u_n)|^2}$$

(2.10)

for any orthonormal basis $u_1, \ldots, u_n$ of $T_xM$. For each Lagrangian submanifold $L$ we can define a phase function $\alpha_L : L \to S^1$ by

$$\alpha_L(x) = \frac{\eta(v_1, \ldots, v_n)^2}{|\eta(v_1, \ldots, v_n)|^2}$$

(2.11)

for any orthonormal basis $v_1, \ldots, v_n$ of $T_xL$.

**Alternative Definition 2.8.3.** A grading of $L$ is a choice of a real valued function $\tilde{L}$ such that $\alpha_L = \exp(2\pi i \tilde{L})$.

For a pair of transversely intersecting graded Lagrangians $L_0, L_1$ and $x \in L_0 \cap L_1$ one can set

$$\deg(x) = \frac{n}{2} + \tilde{L}_0(x) - \tilde{L}_1(x).$$

(2.12)

We denote by $L\{m\}$, $L$ with its grading shifted by $m$, i.e. $\tilde{L}\{m\} = \tilde{L} - m$. A grading for a diffeomorphism $\phi$ from $M$ to itself is a choice of a function
\( \tilde{\phi} : M \to \mathbb{R} \) such that \( \exp(2\pi i \tilde{\phi}(x)) = \alpha_M(x)/\alpha_M(\phi^{-1}(x)) \). \( \phi(L) \) has a preferred grading given by

\[
\tilde{\phi}(L)(x) = \tilde{L}(\phi^{-1})(x) + \tilde{\phi}(\phi^{-1}(x)).
\] (2.13)

A choice of grading for \( \phi \) induces a grading on the graph \( \Gamma \) of \( \phi \):

\[
\tilde{\Gamma}(x, \phi(x)) = \tilde{\phi}(x).
\] (2.14)

Let \( L = (L_{0,1}, \ldots, L_{n-1,n}) \) be a Lagrangian correspondence and assume that \( L_{i,i+1} \subset M_i^- \times M_{i+1} \). Assume we have chosen a trivialization \( \eta_{M_i} \) for the canonical bundle of \( M_i \).

**Definition 2.8.4.** A grading on \( L \) is a lift \( \tilde{L}_{i,i+1} \) of \( \alpha_{L_{i,i+1}} \) for each \( i \) where the phase functions \( \alpha_{L_{i,i+1}} \) are with respect to \( \eta_{M_i^-} \wedge \eta_{M_{i+1}} \).

If \( M_i, i = 0, 1, 2 \) have trivial canonical bundle and we have chosen trivializations \( \eta_{M_i} \) for each \( i \) then gradings \( \tilde{L}_{0,1} \) and \( \tilde{L}_{1,2} \) determine a grading on

\[
L_{0,2} = L_{0,1} \circ L_{1,2}
\]

with regard to the trivialization \( \eta_{M_0} \wedge \eta_{M_2} \), given by

\[
\tilde{L}_{0,2}(m, m'') = \tilde{L}_{1,2}(m', m'') + \tilde{L}_{0,1}(m, m')
\] (2.15)

where \( m' \) is the unique point such that \( (m, m', m', m'') \in (L_{0,1} \times L_{1,2}) \cap M_0 \times \Delta_{M_1} \times M_2 \) provided that the composition is embedded.

Assume we have chosen a trivialization \( \eta_M \) for the canonical bundle of \( M \). The canonical bundle of \( M^- \) is the dual of \( \bigwedge^{\dim M} TM \). Thus we can take \( \sqrt{-1} \eta^{-1} \) as a trivialization of the determinant bundle of \( M^- \). So the phase function of a Lagrangian \( L \subset M \) is the negative of the inverse of the phase function of the same Lagrangian as a subset of \( M^- \). (We denote the later one by \( L^- \).) Therefore a grading \( \tilde{L} \) of \( L \) as a Lagrangian submanifold of \( M \) induces, in a natural way, a grading of \( L \) as a submanifold of \( M^- \). This new grading equals \( k/2 - \tilde{L} \) for some integer \( k \). We choose \( k = n = \dim L \) therefore we have

\[
\tilde{L} = \frac{n}{2} - \tilde{L}.
\] (2.16)
2.9 Stein manifolds

The symplectic manifolds used in the construction of the symplectic tangle invariant are not compact. However they possess plurisubharmonic functions which enable us to prove compactness for pseudoholomorphic surfaces. First of all a Stein manifold is exact as defined below.

Definition 2.9.1. A symplectic manifold \((M, \omega)\) is called exact if there is a one form \(\theta\) on \(M\) such that \(\omega = d\theta\). A Lagrangian submanifold \(L\) of such a manifold is called exact if there is a function \(K\) on \(L\) such that \(\theta|_L = dK\).

In particular if \(H^1(L) = 0\) then \(L\) is exact. An application of Stokes theorem shows that a pseudoholomorphic disk with boundary on an exact Lagrangian submanifold has zero energy and so is constant. Therefore disc bubbling does not occur when one is concerned with the Floer cohomology of such Lagrangians.

Definition 2.9.2. \((M, \psi)\) is called a Stein manifold if \(M\) is a complex manifold and \(\psi\) is a proper function which is bounded below and such that \(-dd^c\psi\) is a symplectic form on \(M\).

For a subset \(N \subset M\), we denote by \(N_{\leq c} (N_c, N_{\geq c})\) the intersection of \(N\) with sublevel (level, superlevel) sets of \(\psi\). Also set \(\theta = -d^c\psi\).

Definition 2.9.3. A Lagrangian submanifold \(L \subset M\) is called \(c\)-allowable if it is exact and \(\psi|_L\) does not have any critical points in \(M_{\geq c}\). It is called allowable if it is \(c\)-allowable for some \(c\). A generalized correspondence \((L_{k,k-1}, \ldots, L_{1,0})\), with \(L_{i,i-1} \subset M_i^- \times M_{i-1}\), is called allowable if the \(M_i\) are Stein and all the \(L_{i,i+1}\) are allowable.

Note that this implies that \(L\) intersects the level sets of \(\psi\) transversely at infinity. Compact Lagrangian submanifolds of Stein manifolds are evidently allowable. Let \(Z = \nabla \psi\) be the Liouville vector field on \(M\). Denote by \(\kappa : \mathbb{R} \times M \to M\) the flow of \(Z\).
Definition 2.9.4. A Lagrangian \( L \) in a Stein manifold \( M \) is said to have a conical end if there is a constant \( c \) such that \( L \) intersects \( M_c \) transversely and \( \kappa([0, \infty) \times (L \cap M_c)) \) equals \( L_{\geq c} \).

An exact Lagrangian with conical end is clearly allowable. Our next task is to assign a Lagrangian with conical end to an allowable Lagrangian which can replace the latter when Floer cohomology is concerned. We first need some definitions.

Definition 2.9.5. A Lagrangian submanifold \( \Lambda \) of the symplectic manifold \( M \leq c \) is called \( \kappa \)-compatible if it intersects \( M_c \) transversely (possibly empty) and there is an \( \epsilon > 0 \) such that \( \kappa([-\epsilon, 0] \times \Lambda_c) = (c-\epsilon, \Lambda \leq c) \).

Definition 2.9.6. A Hamiltonian isotopy induced by a time-dependent function \( H_t \) is called conical if there is a constant \( c \) such that \( H_t \circ \kappa(r, x) = rH_t(\kappa(0, x)) \) for all \( r \geq 0 \), \( t \in [0, 1] \) and \( x \) in \( M_{\geq c} \).

Let \( \phi_t \) be a one parameter family of symplectomorphisms of \( M \) and \( L \subset M \) a Lagrangian submanifold. The isotopy \( \phi_t(L) \) is called exact if \( \phi_t^* \theta|_L = \theta|_L + dK_t \) for any \( t \in [0, 1] \) where \( K_t \) is a function on \( L \) depending smoothly on \( t \). We have the following facts from [16] Section 5.

Lemma 2.9.7. i) Any exact Lagrangian in \( M_{\leq c} \) which intersects the boundary transversely can be exact-isotoped, relative to boundary, in \( M_{\leq c} \) to a \( \kappa \)-compatible one.

ii) If \( \Lambda_t \) is a Lagrangian isotopy in \( M_{\leq c} \) such that all \( \Lambda_t \) intersect the boundary transversely and \( \Lambda_0, \Lambda_1 \) are \( \kappa \)-compatible then there is another isotopy \( \Lambda'_t \) with the same endpoints such that \( \Lambda_t \cap M_c = \Lambda'_t \cap M_c \) for any \( t \in [0, 1] \) and all \( \Lambda_t \) are \( \kappa \)-compatible. If \( \Lambda_t \) is exact, \( \Lambda'_t \) can be chosen to be so.

We include the proof for completeness.

Proof. [16], Lemma 5.2 i)Let \( L \) be such a Lagrangian. Choose \( r < c \) such that \( K = L_{\geq -r} \) deformation retracts onto \( \partial L \). \( \theta|_K \) is closed and vanishes on the boundary so \( \theta|_K = df \) for some \( f \) on \( K \) which vanishes on the boundary. Extend
f to a smooth function \( h \) on \( M_{\leq c} \) vanishing on the boundary and set \( \theta_t = \theta - tdh \) for \( t \in [0, 1] \). Let \( Z_t \) be a vector field such that \( \iota_{Z_t} \omega = \theta_t \). Since \( d\theta_t = \omega \), \( Z_t \) is symplectic and defines an embedding \( \kappa_t : M_c \times [0, \infty] \to M_{\leq c} \). Let \( U \) be a neighborhood of \( M_c \) which lies in the image of \( k_t \) for all \( t \) and deformation retracts onto \( M_c \). Set \( X_t = \partial \kappa_t / \partial t \circ (\kappa_t)^{-1} |_U \). It is a symplectic vector field which vanishes on \( \partial M \). \( \iota_{X_t} \omega \) is closed and vanishes on boundary so equals \( dH_t \) for some \( H_t \) on \( U \) vanishing on \( \pi_c \). Each \( X_t \) can be extended to a Hamiltonian vector field \( \tilde{X}_t \) on \( M_{\leq c} \). Let \( \phi_t \) be the flow of the time dependent vector field \( (\tilde{X}_t) \). We have \( \phi_t \circ \kappa_0 = \kappa_t \) on a neighborhood of \( M_c \) so \( \phi_t^* \theta = (\kappa_0^{-1})^* \kappa_t^* \theta = \theta_1 \) near \( M_c \). Therefore
\[
\phi_t^*(\theta|_L) = \theta_1|_L = 0
\] (2.17)
near the boundary of \( L \) and so \( \phi_1(L) \) is \( \kappa \)-compatible. By (2.17), \( (\phi_t(L)) \) is exact.

ii) It is just a parameterized version of i).

\( \square \)

**Lemma 2.9.8.** Any exact Lagrangian isotopy, relative to boundary, in \( M_{\leq c} \) which consists only of \( \kappa \)-compatible Lagrangians can be embedded into a Hamiltonian isotopy.

The proof is similar to the proof of the fact that a symplectomorphism of zero flux is Hamiltonian.

**Definition 2.9.9.** Let \( L \) be a \( c \)-allowable Lagrangian in \( M \), we take \( \Lambda = L_{\leq c} \), isotope \( \Lambda \) to a \( \kappa \)-compatible \( \Lambda' \) and denote by \( \mathcal{C}_c(L) \subset M \) the Lagrangian with conical end associated to \( \Lambda' \). This means that \( \mathcal{C}_c(L)_{> c} \) is the image of \( L_c \) under the Liouville flow.

It follows from the above lemmas that \( \mathcal{C}_c(L) \) is well-defined up to conical Hamiltonian isotopy. Moreover if \( L_{\leq c} \) and \( L'_{\leq c} \) are exact isotopic, relative to boundary, then \( \mathcal{C}_c(L) \) and \( \mathcal{C}_c(L') \) are conical Hamiltonian isotopic.
If the $M_i$ are Stein and the Lagrangian correspondences have conical ends then it is easy to see that their composition has a conical end as well. Therefore we have the following.

$$\mathcal{C}_c(L_{0,1}) \circ \mathcal{C}_c(L_{1,2}) \simeq \mathcal{C}_c(L_{0,1} \circ L_{1,2})$$ (2.18)

**Definition 2.9.10.** The Stein category has Stein manifolds as objects. Morphisms are given by equivalence classes of allowable generalized Lagrangian correspondences $(L_{0,1}, \ldots, L_{n-1,n})$. The equivalence relation on correspondences is the one in the symplectic category with the difference that we restrict the first kind of equivalence to include only exact isotopies.

### 2.10 Floer cohomology for Lagrangian correspondences

Let $L$ be a generalized Lagrangian correspondence as in the last section. By adding a trivial Lagrangian correspondence (i.e. the diagonal) if necessary we can assume that $n = 2k + 1$ is odd. Define

$$\mathcal{L}_0 = L_0 \times L_{1,2} \times \cdots L_{2k-1,2k}$$ (2.19)

and

$$\mathcal{L}_1 = L_{0,1} \times L_{2,3} \times \cdots \times L_{2k+1}$$ (2.20)

which are Lagrangian submanifolds of $M = M_0 \times M_1 \times \cdots M_n$. If $L_0$ and $L_1$ satisfy $L1$ and $L2$ from section 2.7 one can associate to $L$ the Floer cohomology group

$$HF(L) := HF(\mathcal{L}_0, \mathcal{L}_1).$$ (2.21)

In order for Floer cohomology to define a well-defined map on the symplectic category, we must understand the effect of composition of Lagrangian correspondences on Floer cohomology. The following important *Functoriality Theorem* is proved in [39].
Theorem 2.10.1 (Wehrheim, Woodward [39]). Let \( L = (L_0,1, L_{1,2}, \ldots , L_{n-1,n}) \) be a generalized Lagrangian correspondence between manifolds \( M_0, \ldots , M_n \) such that for some \( 0 < j < n \) the composition \( L_{j,j+1} \circ L_{j-1,j} \) is embedded. Denote
\[
L' = (L_0, \ldots , L_{j,j+1} \circ L_{j-1,j}, \ldots , L_n).
\]
Assume the \( M_i \) are compact and monotone with the same monotonicity constant and all \( L_{i,i+1} \) as well as (2.19) and (2.20) are monotone. Assume in addition that each \( L_{i,i+1} \) is oriented, relatively spin, graded and its minimal Maslov number is at least three. Then with the induced grading and relative spin structure on \( L_{i,i+1} \circ L_{i-1,i} \) there is a canonical isomorphism
\[
HF(L) \cong HF(L')
\]
(2.22)
of graded abelian groups.

2.11 Floer cohomology for exact Lagrangian correspondences

Here we discuss Floer cohomology for exact Lagrangians whose detail is a bit different from that of compact Lagrangians discussed in sections 2.7 and 2.10. The Lagrangians used in the definition of our invariant are exact. Let \( L \) be a generalized Lagrangian correspondence between Stein manifolds and let \( \mathcal{L}_0 \) and \( \mathcal{L}_1 \) be as in (2.19) and (2.20). We want to see when
\[
HF(L) := HF(\mathcal{C}_c(\mathcal{L}_0), \mathcal{C}_c(\mathcal{L}_1))
\]
(2.23)
for some \( c \) large enough is well-defined.

First we assume that there is a conical Hamiltonian isotopy of \( M \) which makes \( \mathcal{L}_0 \) and \( \mathcal{L}_1 \) intersect transversally at finitely many points. We call this assumption finite intersection of the Lagrangians. It holds if one of the Lagrangians is compact. More generally it holds if one of the correspondences \( L_{i,i+1} \) is compact and all the others are proper in the following sense.

Definition 2.11.1. A correspondence \( L \subset M^- \times M' \) is called proper if for each point \( y \in M' \) the set \( \{ x \in M | (x, y) \in M' \} \) is compact.
We denote the isotoped Lagrangians by the same notation. Let $J_i$ be a compatible almost complex structure on $M_i$. If $M_i$ is Stein then we require $J_i$ to be invariant under the flow of Liouville vector field outside a compact set. We call such an almost complex structure \textit{asymptotically invariant}. From the $J_i$ we get an almost complex structure

$$J = (-J_0, J_1, \ldots, (-1)^{n-1}J_n)$$
onumber

on $M$. Let $x, y \in L_0 \cap L_1$ and let $J_t$ be a one parameter family of almost complex structures on $M$ for which there is an $r_0 > 0$ such that $J_t = J$ outside $M \leq r_0$ for all $t$. Denote by $\mathcal{M}(x, y)$ the moduli space of the strips

$$u : \mathbb{R} \times [0, 1] \to Y$$

such that $\frac{\partial}{\partial t} u(s, t) = J_t \frac{\partial}{\partial s} u(s, t)$ and $u(s, i) \in L_i$ for $i = 0, 1$ and $u(-\infty, t) = x, u(\infty, t) = y$. $\mathbb{R}$ acts on $\mathcal{M}(x, y)$ by shifting the parametrization.

Consider the abelian group $CF(L_0, L_1)$ generated freely by the intersection points of the two Lagrangians. The following differential makes $CF(L_0, L_1)$ into a chain complex and the Floer cohomology $HF(L_0, L_1)$ is defined to be the cohomology of this complex.

$$\partial x = \sum_{y \in L_0 \cap L_1} \# \mathcal{M}_1(x, y) / \mathbb{R}$$

(2.24)

Here $\mathcal{M}_1(x, y)$ is the one dimensional part of the moduli space. The count is a priori in $\mathbb{Z}/2$. To be able to define Floer cohomology groups as $\mathbb{Z}$ one needs coherent orientations on the moduli spaces cf. 2.6.2. For this invariant to be well-defined one has to take care of the following issues: transversality of moduli spaces, nonexistence of bubbling, compactness and invariance under Hamiltonian isotopy. In the following discussion we assume that the first two criteria hold and focus on the last two. First compactness.
Lemma 2.11.2. Assume \((M, \psi)\) is a Stein manifold, \(\mathcal{L}_0, \mathcal{L}_1\) are \(C\)-allowable Lagrangians for some \(C \geq r_0\) and that \(M_{\leq C}\) contains the intersection points of the Lagrangians. Then for any Riemann surface \(S\) with boundary and any \(J\)-holomorphic map \(u : S \to M\) with \(u(\partial S) \subset \mathcal{L}_0 \cup \mathcal{L}_1\), the image of \(u\) lies in \(M_{\leq C}\) (which is independent of \(S\) and \(u\)).

Proof. [2], [25] For \(u \in \mathcal{M}(x, y)\), \(\psi \circ u\) cannot have a maximum on the interior of the curve outside \(M_{\leq C}\) by the maximum principle. This is because \(u\) is \(J\) holomorphic outside \(M_{\leq r_0}\). Assume it has a maximum on a boundary point \(p\) i.e. \(\max \psi \circ u = \psi \circ u(p) = R > C\). We can pick holomorphic coordinates on \(S\) in a neighborhood of \(p\) and therefore regard \(u, \) in a neighborhood of \(p = (s_0, 1)\), as a function on some rectangle \([l_1, l_2] \times [1 - \delta, 1]\). We have \(d\psi(\frac{\partial}{\partial s}u)(s_0, 1) = 0\). So \(\frac{\partial}{\partial s}u(s_0, 1) \in T\mathcal{L}_1 \cap TM_R\). By assumption the intersection is transverse therefore it is Legendrian so \(d\psi(J \frac{\partial}{\partial s}u(s_0, 1)) = 0\). But we have \(\frac{\partial}{\partial s}u = J \frac{\partial}{\partial s}u\) so \(d\psi(\frac{\partial}{\partial s}u)(s_0, 1) = 0\). This contradicts the strong maximum principle which implies \(d\psi(\frac{\partial}{\partial s}u) > 0\).

This enables us to apply the rescaling argument to show that the limit of a bounded energy sequence of such curves is either a broken trajectory or a curve with sphere or disc bubbles. Therefore we can compactify \(\mathcal{M}(x, y)\) by adding these limiting curves to it. If in addition both \(M\) and the Lagrangians are exact, no bubbling occurs and so the sum in (2.24) is finite and we get \(\partial^2 = 0\).

Proposition 2.11.3. i) Let \(L, L'\) be two Lagrangians in a Stein manifold \((M, \psi)\) which are \(C\)-allowable and satisfy the finite intersection condition. Then the Floer cohomology \(HF(\mathcal{C}_c(L), \mathcal{C}_c(L'))\) is well-defined. It is independent of \(c\) when \(c > C\) and \(L \cap L' \subset M_{\leq C}\).

ii) If \(\{\phi_t\}_{t \in [0,1]}\) is a Hamiltonian flow such that \(\cup_t \phi_t(L) \cap L'\) is contained in \(M_{\leq C'}\) then for \(c > C'\), \(HF(\mathcal{C}_c(L), \mathcal{C}_c(L'))\) is canonically isomorphic to \(HF(\mathcal{C}_c(\phi_1(L)), \mathcal{C}_c(L'))\).
Proof. Part i) follows from Lemma 2.11.2 along with the results in section 2.9. Independence of $c$ follows from Lemma 2.11.2. For part ii) let $H$ be the Hamiltonian function inducing $\phi$ and $H'$ be a function which equals $H$ on $M_{\leq C'}$ and is zero outside $M_{\geq c}$. If $\phi'$ is the flow of $H'$ then $\mathcal{C}_c(\phi(L)) = \mathcal{C}_c(\phi'(L))$. Since $\phi'$ is compactly supported, with the help of Lemma 2.11.2 we can apply the usual invariance argument using the solutions of perturbed Cauchy-Riemann equation.

Proposition 2.11.4. If the $M_i$ are Stein, $L$ is allowable and satisfies the finite intersection condition and each $L_{i,i+1}$ is relatively spin then (2.22) holds.

Proof. It is easy to see that the generators for the two Floer groups are in one-to-one correspondence. Take $x, y \in L_0 \cap L_1$ and let $\mathcal{M}_\delta(x, y)$ be the moduli space of pseudoholomorphic strips $u = (u_0, \ldots u_n)$ where

$$u_i : [0, 1] \times \mathbb{R} \rightarrow M_i$$

if $i \neq j$ and $u_i : [0, \delta] \rightarrow M_j$ and with boundary condition for $u$ given by $L$ and with $x$ and $y$ as asymptotic points. Let $\mathcal{M}'(x, y)$ be the moduli space of strips

$$(u_0, \ldots, u_{i-1}, u_{i+1}, \ldots, u_n) : [0, 1] \times \mathbb{R} \rightarrow M_0 \times \cdots \times M_n$$

with boundary condition $L'$ and asymptotic points $x, y$. Since the $M_i$ are Stein and the Lagrangians are allowable and satisfy the finite intersection property then Lemma 2.11.2 implies that the holomorphic curves in $\mathcal{M}_\delta(x, y)$ and $\mathcal{M}'(x, y)$ stay in a compact submanifold of $M_0 \times \cdots \times M_n$ (which doesn’t depend on $\delta$) and so the proof proceeds as in [39] to show that for $\delta$ small enough the two moduli spaces are bijective. Note that exactness of the $L_{i,i+1}$ implies monotonicity and rules out bubbling so we do not need the assumption on the minimal Maslov index in 2.10.1.

Remark 2.11.5. Assume we have two Hamiltonian isotopic Lagrangian correspondences $L_0, L_1$ and another correspondence $L'$ such that both compositions $L_0 \circ L'$ and $L_1 \circ L'$ are embedded. In general we do not know if $L_0 \circ L'$ and
$L_1 \circ L'$ are Hamiltonian isotopic or not. However the proof of the Functoriality Theorem implies that Floer cohomology is invariant under such an isotopy.
Chapter 3

Khovanov homology for tangles

3.1 Tangles

A tangle $T$ is defined to be a compact one-dimensional submanifold of (a diffeomorphic image of) $\mathbb{C} \times [0, 1]$ such that $i(T) := T \cap (\mathbb{C} \times \{0\}) \subset \mathbb{R} \times \{0\}$ and $t(T) := T \cap (\mathbb{C} \times \{1\}) \subset \mathbb{R} \times \{1\}$ and both sets are finite. The second assumption makes $i(T)$ and $t(T)$ ordered sets. In this thesis we deal only with tangles with an even number of initial points and end points. Such tangles are called even tangles. If $\#i(T) = 2m$, $\#t(T) = 2n$ we say $T$ is an $(m, n)$-tangle and write $mTn$. We also allow $m$ and/or $n$ to be zero.

Definition 3.1.1. Two tangles $T, T'$ are called equivalent if there is a continuous family $T_t$ of tangles for $t \in [0, 1]$ such that $T_0 = T$ and $T_1 = T'$ and the order of $i(T_t)$ and of $t(T_t)$ is fixed.

Two tangles $T_1, T_2$ can be composed (concatenated) if $t(T_1) = i(T_2)$. Two equivalence classes $[T_1]$ and $[T_2]$ of tangles can be composed if $\#t(T_1) = \#i(T_2)$ and composition is done using the ordering on $t(T_1)$ and $i(T_2)$. Composition of tangles is denoted by juxtaposition. We will use the notation $id_m, \cap_{im}, \cup_{im}$.

Figure 3.1: A $(1, 1)$-tangle
and $\sigma_{i,m}$ for the elementary tangles in Figures 3.2 and 3.3 where $m$ denotes the number of the strands. We might ignore $m$ when there is no confusion. When we say a tangle $T$ is equivalent to, say, $\cap_{i,m}$, we implicitly have a one to one correspondence between $i(T)$ and $\{1, 2, \ldots, 2m - 2\}$ and also between $t(T)$ and $\{1, 2, \ldots, 2m\}$ in mind.

A decomposition of $T$ is a sequence of tangles
\[ n_0T_1n_1T_2\ldots n_{l-1}T_ln_l \quad n_0 = m, n_l = n \] such that $T$ is equivalent to $T_1T_2\cdots T_l$. A Morse-theoretic argument shows that any $T$ can be expressed (not uniquely) as a composition of elementary tangles. Crossingless matchings (section 4.5) are a special class of $(0, n)$ or $(n, 0)$-tangles. Given a set of $2n$ points on the plane, a crossingless matching is a set of $n$ nonintersecting curves each joining a pair of the given points. In the context of tangles a crossingless matching is regarded as a subset of $\mathbb{C} \times [0, 1]$.

**Definition 3.1.2.** Let $\mathcal{C}_n$ be the set of isotopy (in $\mathbb{C}$) classes of crossingless matchings between $2n$ points on the real line all of whose arcs lie in the upper half plane.

The cardinality of $\mathcal{C}_n$ equals the $n$th Catalan number.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure32.png}
\caption{The braids $\sigma_i$ and $\sigma^t_i$}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure33.png}
\caption{$\cap_{i,m}$, $\cup_{i,m}$ and $id_m$}
\end{figure}

One can define a category $\text{Tang}$ whose objects are natural numbers and $\text{hom}(m, n)$ consists of equivalence classes of $(m, n)$-tangles. $\text{Tang}$ has a monoidal
structure given by putting two tangles $kTl$ and $mTn$ “side-by-side” to obtain a $(k + m, l + n)$-tangle. We denote this by $T \oplus T'$. To each $(m, n)$-tangle $T$ there is assigned a “mirror image” $T^t$ which is a $(n, m)$-tangle. There is a generators and relations description of Tang due to Yetter [42] whose proof relies on Reidemeister’s description of plane diagram moves.

**Lemma 3.1.3** (Yetter [42]). The following are all the commutation relations between elementary tangles where “$=$” means equivalence. If $|i − j| > 1$ we have:

\[
\begin{align*}
\sigma_i \sigma_j &= \sigma_j \sigma_i \quad (3.2) \\
\cap_i \cup_j &= \cup_j \cap_i \quad (3.3)
\end{align*}
\]

and for any $i$ we have:

\[
\begin{align*}
\sigma_i \cup_i &= \cup_i \quad (3.5) \\
\sigma_i \sigma_i^t &= id \quad (3.6) \\
\sigma_i \sigma_{i+1} \sigma_i &= \sigma_{i+1} \sigma_i \sigma_{i+1} \quad (3.7) \\
\cap_{i,m} \cup_{i+1,m} &= id_{m-1} \quad (3.8)
\end{align*}
\]

\[
\begin{align*}
\sigma_i \cup_{i+1} &= \sigma_{i+1}^t \cup_i \\
\sigma_i^t \cup_{i+1} &= \sigma_{i+1} \cup_i.
\end{align*}
\]

Given two decompositions of two equivalent tangles, the following lemma provides a natural way of converting one to the other.

**Lemma 3.1.4.** If $T, T'$ are two equivalent tangles and $D : T = T_1T_2 \cdots T_m, D' : T' = T'_1T'_2 \cdots T'_m$ are decompositions into elementary tangles then one decomposition can be converted to the other by a sequence of the moves described in Lemma 3.1.3.

**Proof.** We can regard each decomposition as being inside $\mathbb{C} \times [0, 1]$. We can also find Morse functions $f, f'$ on $T$ and $T'$ respectively such that the decomposition
of $T$ (resp. $T'$) by critical sets of $f$ (resp. $f'$) yields $D$ (resp. $D'$); in other words $f$ has critical points separating each $T_i$ from $T_{i+1}$ and no more. There is a diffeomorphism $\phi$ of $\mathbb{C} \times [0,1]$ such that $\phi(T) = T'$. The reason is that because $T$ and $T'$ are equivalent, there is a family $T(t)$ of tangles with the same boundary points such that $T(0) = T, T(1) = T'$. Because strands of $T(t)$ never intersect, we can obtain a time dependent vector field on $T(t)$ by differentiation. This vector field can be smoothly extended to $\mathbb{C} \times [0,1]$. Let $\phi$ be the time one map of this vector field. Then $\phi(T) = T'$.

Let $f'' = \phi^* f'$ and $T_i'' = \phi^{-1}(T_i')$. So we get a decomposition $D'' : T_1'', \ldots, T_m''$ of $T$ induced by $f''$. According to Cerf theory [1], there is a family $f_t$ of smooth functions such that $f_0 = f, f_1 = f''$ and $f_t$ is Morse except for finitely many times $t_1, \ldots, t_k$ and at each $t_i$ a pair of canceling critical points is introduced or deleted. Since $T$ is one dimensional, each $t_i$ has the effect of either (1) merging two adjacent handles (i.e. two adjacent elementary tangles) or decomposing one into two or (2) the effect of the move (3.8) above. In the first case the effect of merging two adjacent handles and then separating into two new ones is equivalent to one of the moves in Lemma 3.1.3.

Now between each $t_i, t_{i+1}$, each handle can be isotoped to an equivalent one. The only way this can change the decomposition is by changing the value of $f_t$ at critical points and thereby changing the order of the critical points in the decomposition. This also has the effect of commuting the handlebodies in the decomposition.

The invariant that we define in this thesis is an invariant of oriented tangles. An oriented tangle comes with an orientation of each one of its components. Two example are shown in Figure 3.4. When considering commutation relations between tangles we ignore the orientation.
3.2 The TQFT

Khovanov homology is based on a 1+1 dimensional TQFT $\mathcal{F}$ whose definition we review here. 1+1 dimensional TQFTs are in one-to-one correspondence with Frobenius algebras. Khovanov [14] defines the Frobenius algebra $\mathcal{V}$ to be equal to $H^*(S^2)\{-1\}$ (i.e. the cohomology of $S^2$ with its grading shifted down by one) as a ring. Let $1, X$ be degree $-1$ and degree 1 generators of $\mathcal{V}$ respectively. We define comultiplication by

$$\Delta(X) = X \otimes X \quad \Delta(1) = 1 \otimes X + X \otimes 1.$$  \hspace{1cm} (3.10)

The unit map $\iota : \mathbb{Z} \to \mathcal{V}$ by $\iota(1) = 1$. The trace map is defined by

$$\epsilon(X) = 1 \quad \epsilon(1) = 0.$$  \hspace{1cm} (3.11)

It is evident that multiplication is given by

$$m(1, X) = m(X, 1) = X \quad m(X, X) = 0 \quad m(1, 1) = 1.$$  \hspace{1cm} (3.12)

Definitions above are made by choosing a basis for $H^*(S^2)$. In section 7.3 we give a definition which does not need the choice of a basis. The TQFT $\mathcal{F}$ assigns to each closed one dimensional manifold (i.e. a circle) the vector space $\mathcal{V}$, to each cap the unit map $\iota : \mathbb{Z} \to \mathcal{V}$, to each cup the trace map $\epsilon : \mathcal{V} \to \mathbb{Z}$, to each pair of pants the multiplication $m : \mathcal{V} \otimes \mathcal{V} \to \mathcal{V}$, and to each reverse pair of pants the comultiplication $\Delta : \mathcal{V} \to \mathcal{V} \otimes \mathcal{V}$. 

![Oriented braids $\sigma^+$ and $\sigma^-$](image_url)
3.3 Tangle cobordisms and the rings $H^m$

We denote the Cartesian coordinates on $\mathbb{C} \times [0, 1] \times [0, 1]$ by $(z, t, s)$. For a subset $A \subset (\mathbb{C} \times [0, 1] \times [0, 1])$ we set

$$\partial^v_i A = A \cap (\mathbb{C} \times [0, 1] \times \{i\})$$

and

$$\partial^h_i A = A \cap (\mathbb{C} \times \{i\} \times [0, 1]).$$

**Definition 3.3.1.** Let $T_0, T_1$ be two $(m, n)$-tangles. A cobordism between $T_0$ and $T_1$ is a smoothly embedded surface $S$ in $\mathbb{C} \times [0, 1] \times [0, 1]$ s.t.

$$\partial^v_i S = T_i$$

for $i = 0, 1$. We also require $S$ to be the product of $\partial^h_i$ or $\partial^v_i$ with a small subinterval in a neighborhood of each face of $\mathbb{C} \times \partial([0, 1] \times [0, 1])$.

The identity cobordism between $T$ and itself is denoted by $1_T$. Tangle cobordisms can be composed in two ways. First the **vertical composition**: if $S, S'$ are cobordisms between $T_0, T_1$ and $T_1, T_2$ then we get a cobordism

$$S' \circ S = \frac{S' \cup S}{\partial^h_0 S' \sim \partial^v_1 S}$$

between $T_0$ and $T_1$. Secondly the **horizontal composition**: if $S$ is a cobordism between $kT_0l$ and $mT_1n$, and $S'$ is a cobordism between $lT_0'L$ and $nT_1'N$ then we get a cobordism

$$S'S = \frac{S' \cup S}{\partial^h_0 S' \sim \partial^v_1 S}$$

between $kT_0' \circ T_0L$ and $mT_1' \circ T_1N$. The last assumption in the definition of a cobordism ensures that compositions are smooth embedded surfaces.

For the purpose of this paper we just need to consider a special class of tangle cobordisms.

**Definition 3.3.2.** For a crossingless matching $a \in C_m$, the minimal cobordism between $a^*a$ and $id_m$ is the one which is given by merging the corresponding strands
of $a'$ and $a$ from the outermost one to the innermost one as depicted in Figure 3.5. We denote this minimal cobordism by $S_a$.

\begin{figure}[h]
\centering
\includegraphics[width=0.7\textwidth]{figure3.5.png}
\caption{A minimal cobordism}
\end{figure}

For $a, b \in C_m$ set
\[
aH_b^m = \mathcal{F}(a'b)\{m\}
\]  
and
\[
H^m = \bigoplus_{a,b \in C_m} aH_b^m.
\]

Note that $a'b$ is a disjoint union of circles so $aH_b^m = \mathcal{V}^\otimes k$ where $k$ is the number of the circles. Multiplication
\[
aH_b^m \otimes cH_d^m \to aH_d^m
\]
is defined to be zero if $b \neq c$. If $b = c$, let $S_b$ be the minimal cobordism between $b'b$ and $id_m$. The cobordism $1_a^b S_b 1_c$ is a surface without corners so we get a map $\mathcal{F}(1_a^b S_b 1_c) : aH_b^m \otimes bH_c^m \to aH_c^m$ which gives us multiplication.

We now recall a recursive decomposition of $H^m$ from [29]. Denote by $C'_m$ the subset of $C_m$ consisting of elements which contain $\cap_1$, i.e. elements which contain an arc between points 1 and 2, and denote by $C''_m$ its complement. (1 can be replaced with any $1 \leq i \leq 2m - 1$.) $C'_m$ is in one-to-one correspondence with $C_{m-1}$. We have a map $C''_m \to C_{m-1}$, $a \mapsto a'$, given by joining the two strands of $a$ that stem from 1 and 2. Let $CC^1_m \subset C''_m \times C''_m$ be the subset of all $(a, b)$ such that the arcs passing through points 1 and 2 in $a'b$ form a single circle. If $(a, b)$ is in the complement of $CC^1_m$ then the arcs passing through points 1 and 2 in $a'b$ form two circles.
Let $a, b \in C'_m$. If $\bar{a}$ denotes $a$ with the $\cap_1$ removed then we have

$$a H^m_b = \bar{a} H^{m-1}_b \otimes \mathcal{V}\{1\}.$$\

This contributes a summand of $H^{m-1} \otimes \mathcal{V}\{1\}$ to $H^m$. Set

$$\tilde{H}^m = \bigoplus_{a \in C'_m, b \in C''_m} \mathcal{F}(a^t, b)\{m\}.$$\

The embedded circle $C$ in $a^t b$ which passes through points 1 and 2 contributes a factor of $\mathcal{V}\{1+i\}$ to $\tilde{H}^m$ where $i$ is the number of other pairs of points $2k-1, 2k$ which $C$ passes through. We can set

$$\tilde{H}^m = \bar{H}^m \otimes \mathcal{V}\{1\}$$\

where $\mathcal{V}\{1\}$ is the “local” contribution of the circle containing $\cap_1$ or $\cup_1$. This means that if $a \in C'_m, b \in C''_m$ and we modify the strands of $a^t b$ passing through 1 and 2 only in a small neighborhood of the points 1 and 2 then we alter only the second factor in $\bar{H}^m \otimes \mathcal{V}\{1\}$. Also denote by $\tilde{H}^m_1$ and $\tilde{H}^m_2$ the contribution of $\mathcal{C}_m^1$ and its complement to $H^m$. Again we can write $\tilde{H}^m_1 = H^m_1 \otimes \mathcal{V}\{1\}$ and $\tilde{H}^m_2 = H^m_2 \otimes \mathcal{V}\{1\} \otimes \mathcal{V}\{1\}$ where $\mathcal{V}\{1\}$ resp. $\mathcal{V}\{1\} \otimes \mathcal{V}\{1\}$ are “local” contributions from the single circle resp. the two circles formed by arcs passing through 1 and 2. Therefore we get

$$H^m = \left( (H^{m-1} \oplus \bar{H}^m \oplus \tilde{H}^m_1 \oplus \tilde{H}^m_1) \otimes \mathcal{V}\{1\} \right) \bigoplus \tilde{H}^m_2 \otimes \mathcal{V}\{1\} \otimes \mathcal{V}\{1\}. \quad (3.17)$$\

as abelian groups.

### 3.4 The Khovanov invariant for flat tangles

**Definition 3.4.1.** A flat tangle is a tangle which can be embedded into the plane i.e. a tangle without crossings.

For a flat $(m, n)$ tangle T we define

$$\mathcal{K}(T) = \bigoplus_{a \in C'_m, b \in C''_m} \mathcal{F}(a^t b)\{n\}. \quad (3.18)$$
Obviously $H^m = \mathcal{K}\hat{h}(id_m)$ as abelian groups. The abelian group $\mathcal{K}\hat{h}(T)$ for an $(m,n)$-tangle $T$ has the structure of a $(H^m, H^n)$-bimodule which is given by

$$\mathcal{F}(1_a S_1 1_T 1_c) : a H^m_b \otimes \mathcal{F}(b'Tc) \rightarrow \mathcal{F}(a'Tc) \quad (3.19)$$

for each $a, b, c$ and zero map $a H^m_b \otimes \mathcal{F}(c'Td) \rightarrow \mathcal{F}(a'Td)$ if $b \neq c$.

For the unlinked union $T \sqcup S^1$ we have

$$\mathcal{K}\hat{h}(T \sqcup S^1) = \mathcal{K}\hat{h}(T) \otimes \nu = \mathcal{K}\hat{h}(T)\{1\} \oplus \mathcal{K}\hat{h}(T)\{-1\} \quad (3.20)$$

If $S$ is a cobordism between two flat $(m,n)$-tangles $T_0, T_1$, it induces a bimodule map

$$\mathcal{K}\hat{h}(S) : \mathcal{K}\hat{h}(T_0) \rightarrow \mathcal{K}\hat{h}(T_1) \quad (3.21)$$

which is given on each component by

$$\mathcal{F}(1_a S_1 b) : \mathcal{F}(a'T_0 b) \rightarrow \mathcal{F}(a'T_1 b). \quad (3.22)$$

The fact that $\mathcal{K}\hat{h}(S)$ is independent of the isotopy class of $S$ follows from the same property for the TQFT $\mathcal{F}$. It is obvious that

$$\mathcal{K}\hat{h}(S \circ S') = \mathcal{K}\hat{h}(S) \circ \mathcal{K}\hat{h}(S') \quad (3.23)$$

**Lemma 3.4.2 ([15]).** If $lTm$ and $mT'n$ are flat tangles then

$$\mathcal{K}\hat{h}(T_0 \circ T_1) = \mathcal{K}\hat{h}(T_0) \otimes_{H^m} \mathcal{K}\hat{h}(T_1)$$

as $(H^l, H^n)$-bimodules. If $T_0 S_0 T'_0$ and $T_1 S_1 T'_1$ are minimal cobordisms then

$$\mathcal{K}\hat{h}(S_0 S_1) = \mathcal{K}\hat{h}(S_0) \otimes_{H^m} \mathcal{K}\hat{h}(S_1) \quad (3.24)$$

### 3.5 The Khovanov invariant in general

In this section we present Khovanov’s invariant for general tangles in a roundabout way which is shorter and suitable for our purpose. For a general tangle $T$, $\mathcal{K}\hat{h}(T)$ is a chain complex of graded bimodules over the rings $H^m$ so it is doubly graded. For a flat tangle $T$ the chain complex

$$\cdots \rightarrow 0 \rightarrow \mathcal{K}\hat{h}(T) \rightarrow 0 \rightarrow \cdots \quad (3.25)$$
with $\mathcal{K}(T)$ in (second or homological) degree zero. We denote upward shift in first by $\{i\}$ and downward shift in second grading by $[i]$. The only elementary braids which are not flat are the braids $\sigma^{+}_{i,m}$ and $\sigma^{-}_{i,m}$. Consider the chain complexes

$$C^{+}_{i,m} \rightarrow \cdots \rightarrow \mathcal{K}(id_{m}) \xrightarrow{\alpha} \mathcal{K}(\cup_{i,m} \cap_{i,m}) \{1\} \rightarrow 0 \rightarrow \cdots \tag{3.26}$$

$$C^{-}_{i,m} \rightarrow \cdots \rightarrow \mathcal{K}(\cup_{i,m} \cap_{i,m}) \xrightarrow{\beta} \mathcal{K}(id_{m}) \{1\} \rightarrow 0 \rightarrow \cdots \tag{3.27}$$

where the domain of maps $\alpha$ and $\beta$ are in (second or homological) degree zero.

The map $\alpha$ is $\mathcal{K}(S_{i}) = \oplus_{a,b \in C_{m}} F(1_{a}^{1} S_{i} 1_{b})$ where $S_{i}$ is the minimal cobordism between $\cup_{i,m} \cap_{i,m}$ and $id_{m}$. The map $\beta$ is obtained in the same way from $S_{i}^{t}$ which is a cobordism between $id_{m}$ and $\cup_{i,m} \cap_{i,m}$. The $-1$ degree shift is to make the map $\alpha$ of (the first) degree zero.

Let $\sigma^{+} = \sigma^{+}_{i,m}$ and $\sigma^{-} = \sigma^{-}_{i,m}$ be as in the Figure 3.4. Khovanov defines

$$\mathcal{K}(\sigma^{+}) = C^{+}_{i,m} \{1\} \tag{3.28}$$

$$\mathcal{K}(\sigma^{-}) = C^{-}_{i,m} \{1\}. \tag{3.29}$$

Now let $n_{0}T_{0}n_{1}T_{1}n_{2} \cdots n_{k}T_{k}n_{k+1}$ be a decomposition of a tangle $T$ into elementary tangles.

**Definition 3.5.1.**

$$\mathcal{K}(T) := \mathcal{K}(T_{0}) \otimes_{H^{1}} \mathcal{K}(T_{1}) \otimes_{H^{2}} \cdots \otimes_{H^{n_{k}}} \mathcal{K}(T_{k}) \tag{3.30}$$

In [15], Khovanov defines his invariant using the cube of resolutions and obtains the above equation as a consequence. He also shows that $\mathcal{K}(T)$ is independent of the decomposition and is invariant under isotopies of $T$. If $L$ is a link, the homology of $\mathcal{K}(L)$ is the original Khovanov homology [14] of $L$ with its first grading reversed. We set

$$\mathcal{K}^{i}(T) = \bigoplus_{k+j=i} H(\mathcal{K}(T))^{j,k}. \tag{3.31}$$
Seidel and Smith [35] conjecture that their invariant \( \mathcal{HSS} \) is equal to \( \overline{\mathcal{K}} \).

**Lemma 3.5.2.** i) We have

\[
\overline{\mathcal{K}}(\cup_{i;m} \cap_{i;m}) = \left( \left( H^{m-1} \bigoplus \bar{H}^m \bigoplus \bar{\bar{H}}^m \bigoplus H^1_m \right) \otimes \mathcal{V}\{1\} \otimes \mathcal{V}' \right) \bigoplus H^m_2 \otimes \mathcal{V}\{2\}.
\]

ii) On the first four direct summands, the map \( \alpha : \mathcal{F}(a^i \text{id}_m b) \to \mathcal{F}(a^i \cup_{i;m} \cap_{i;m} b) \) is given by the comultiplication \( \Delta : \mathcal{V}\{1\} \to \mathcal{V}\{1\} \otimes \mathcal{V} \) tensored with the identity map. On the last one it is given by the multiplication \( m : \mathcal{V}\{1\} \otimes \mathcal{V}\{1\} \to \mathcal{V} \) tensored with the identity.

iii) On the first four direct summands, the map \( \beta : \mathcal{F}(a^i \cup_{i;m} \cap_{i;m} b) \to \mathcal{F}(a^i \text{id}_m b) \) is given by the multiplication \( m : \mathcal{V} \otimes \mathcal{V} \to \mathcal{V} \) tensored with the identity map. On the last one it is given by the comultiplication \( \Delta \) tensored with the identity.

iv)

\[
\overline{\mathcal{K}}(\sigma_k^+) = \left( H^{m-1} \bigoplus \bar{H}^m \bigoplus \bar{\bar{H}}^m \bigoplus H^1_m \right) \otimes \mathcal{V}\{-1\} \bigoplus H^m_2 \otimes \mathcal{V}\{2\}
\]

\[
\overline{\mathcal{K}}(\sigma_k^-) = \left( H^{m-1} \bigoplus \bar{H}^m \bigoplus \bar{\bar{H}}^m \bigoplus H^1_m \right) \otimes \mathcal{V}\{3\} \bigoplus H^m_2 \otimes \mathcal{V}\{2\}
\]

**Proof.** i) Follows easily by comparison to (3.17).

ii) This is because in the first four summands the cobordism merges two circles into one and in the last one it decomposes a circle into two.

iii) Similarly because in the first four summands the cobordism decomposes one circle into two and in the last one it merges two circles into one.

iv) Since \( m : \mathcal{V} \otimes \mathcal{V} \to \mathcal{V} \) is surjective we have

\[
H^1(C_{i;m}) = \frac{H^m_2 \otimes \mathcal{V}\{1\} \otimes \mathcal{V}'\{1\}\{-1\}}{H^m_2 \otimes \text{Im } \Delta} = \frac{H^m_2 \otimes \mathcal{V} \otimes \mathcal{V}'\{1\}}{\text{Im } \Delta}.
\]

\( \mathcal{V} \otimes \mathcal{V}'\{1\}/ \text{Im } \Delta \) is isomorphic to \( \mathbb{Z} \times 1 \otimes I, 1 \otimes X - X \otimes I > \{1\} \). Therefore

\[
H^1(C_{i;m}) = H^m_2 \{-1\} \oplus H^m_2 \{1\} \cong H^m_2 \otimes \mathcal{V}.
\]

The map \( \Delta \) is injective and the kernel of \( m : \mathcal{V}\{1\} \otimes \mathcal{V} \to \mathcal{V}'\{1\}\{-1\} \) equals \( \mathbb{Z} \times X \otimes X, I \otimes X - X \otimes I > \). Tensoring with \( X \otimes X \) has the effect of shifting degree
by two, and tensoring with $I \otimes X - X \otimes I$ does not shift the degree. Therefore

$$H^0(C^-_{i,m}) = \left( H^{m-1} \{1\} \bigoplus \tilde{H}^m \{1\} \bigoplus \tilde{H}^m \{1\} \bigoplus H_1^m \{1\} \right) \otimes (\mathbb{Z}\{2\} \oplus \mathbb{Z})$$

which is isomorphic to $(H^{m-1} \bigoplus \tilde{H}^m \bigoplus \tilde{H}^m \bigoplus H_1^m) \otimes \mathcal{V}\{2\}$.

Therefore

$$\overline{Kh}(\sigma^-_k) = (H^0(C^-_{k,m}) \oplus H^1(C_{k,m})\{1\})\{+1\} = (H^{m-1} \bigoplus \tilde{H}^m \bigoplus \tilde{H}^m \bigoplus H_1^m) \otimes \mathcal{V}\{2 + 1\} \bigoplus H_2^m \otimes \mathcal{V}\{2\}$$

Now for $\sigma^+_i$ we have

$$H^0(C^+_{i,m}) = H^m_2 \otimes (\ker m : \mathcal{V}\{1\} \otimes \mathcal{V}\{1\} \to \mathcal{V}\{2\}\{-1\}) = H^m_2 \otimes \mathbb{Z} < X \otimes X, 1 \otimes X - X \otimes 1 > \{2\} \cong H^m_2 \otimes \mathcal{V}\{3\}.$$  

$$H^1(C^+_{i,m}) = (H^{m-1} \bigoplus \tilde{H}^m \bigoplus \tilde{H}^m \bigoplus H_1^m) \otimes \text{coker}(\Delta : \mathcal{V}\{1\} \to \mathcal{V}\{1\} \otimes \mathcal{V}\{-1\})$$

$$= (H^{m-1} \bigoplus \tilde{H}^m \bigoplus \tilde{H}^m \bigoplus H_1^m) \otimes \{1 \otimes 1, 1 \otimes X - X \otimes 1\} \cong (H^{m-1} \bigoplus \tilde{H}^m \bigoplus \tilde{H}^m \bigoplus H_1^m) \otimes \mathcal{V}\{-1\}$$

$$\overline{Kh}(\sigma^+_k) = (H^0(C^+_{k,m}) \oplus H^1(C_{k,m})\{1\})\{-1\} = (H^{m-1} \bigoplus \tilde{H}^m \bigoplus \tilde{H}^m \bigoplus H_1^m) \otimes \mathcal{V}\{-1\} \bigoplus H_2^m \otimes \mathcal{V}\{3 - 1\}$$

$\square$
Chapter 4

The symplectic invariant of tangles

In this chapter we review the construction of Seidel and Smith [35]. Denote by Conf$_m$ the space of all unordered $m$-tuples of distinct complex numbers $(z_1, \cdots, z_m)$. Denote by Conf$_0^m$ the subset of Conf$_m$ consisting of $m$-tuples which add up to zero, i.e. $z_1 + \cdots + z_m = 0$.

4.1 Transverse slices

In this section we review Section 2 of [35]. The basic reference for this material is [36]. Let $G$ be a complex semisimple Lie group and consider the adjoint action of $G$ on its Lie algebra $\mathfrak{g}$. The adjoint quotient map $\chi : \mathfrak{g} \to \mathfrak{g}/G$ sends each element of $\mathfrak{g}$ to its orbit in $\mathfrak{g}/G$. A theorem of Chevalley (See [9], Chapter 23) asserts that the algebraic quotient $\mathfrak{g}//G$ can be identified with $\mathfrak{h}/W$ where $\mathfrak{h}$ is a Cartan subalgebra of $\mathfrak{g}$ and $W$ the associated Weyl group. Therefore $\chi$ can be regarded as assigning to each $y \in \mathfrak{g}$ the eigenvalues (or equivalently coefficients of the characteristic polynomial) of the semisimple part of $y$.

**Definition 4.1.1.** A transverse slice $S$ for the adjoint action at $x \in \mathfrak{g}$ is a locally closed subvariety $S$ of $\mathfrak{g}$ containing $x$ which is invariant under the action of the isotropy subgroup $G_x$, such that $\dim S$ equals the codimension of the orbit of $x$ and such that the morphism

$$\chi : \mathfrak{g} \times S \to \mathfrak{g}, \quad (g, s) \mapsto \text{Ad}_g s$$

is smooth.

It is evident that such an $S$ intersects the orbit of any $y$ sufficiently close to $x$.
transversely. If $K$ is an open submanifold of $G$ containing the identity such that $T_eK$ is complementary to \{ $y \in \mathfrak{g} : [x, y] = 0$ \} then it can be easily seen that any other transverse slice at $x$ lies (locally) in the image of the map

$$\text{Ad} : K \times S \to \mathfrak{g}.$$  \hfill (4.1)

The Jacobson-Morozov lemma \cite{11} tells us that if $x \in \mathfrak{g}$ is nilpotent then there are elements $y, h \in \mathfrak{g}$ such that

$$[x, y] = h \quad [x, h] = -2x \quad [y, h] = 2y.$$

Now we specialize to $\mathfrak{g} = \mathfrak{sl}_2m = \mathfrak{sl}_2m(\mathbb{C})$. In this case $W = S_n$. Consider the vector field $K$ on $\mathfrak{g}$ given by $K(z) = 2z - [h, z]$. It defines a $\mathbb{C}^*$ action on $\mathfrak{g}$ given by $\lambda_r(z) = r^2 e^{-\log(r)h} z e^{\log(r)h}$ for $r \in \mathbb{C}^*$. The vector field $K$ vanishes at $x$ so $x$ is a fixed point of $\lambda_r$. A slice at $x$ is called homogeneous if it is invariant under $\lambda_r$.

Take $x$ to be a nilpotent Jordan matrix of the form $(m, m)$. It can be written as

$$
\begin{pmatrix}
0_{2 \times 2} & 1_{2 \times 2} \\
0_{2 \times 2} & 0_{2 \times 2} & 1_{2 \times 2} \\
\vdots & & \ddots \\
0_{2 \times 2} & 0_{2 \times 2} & \cdots & 0_{2 \times 2} & 1_{2 \times 2} \\
0_{2 \times 2} & 0_{2 \times 2} & \cdots & 0_{2 \times 2} & 0_{2 \times 2} 
\end{pmatrix}
$$

(4.2)

where $1_{2 \times 2}$ and $0_{2 \times 2}$ are the $2 \times 2$ identity matrices respectively. In this case $y$ and $h$ can be chosen to be the following matrices.

$$h = \begin{pmatrix}
(m-1)1_{2 \times 2} \\
(m-3)1_{2 \times 2} \\
\vdots \\
(m-5)1_{2 \times 2} \\
(-m+1)1_{2 \times 2}
\end{pmatrix} \quad (4.3)$$
$$y = \begin{pmatrix}
0_{2 \times 2} & \quad (n-1)1_{2 \times 2} & 0_{2 \times 2} \\
(n-1)1_{2 \times 2} & 2(n-2)1_{2 \times 2} & 0_{2 \times 2} \\
0_{2 \times 2} & 2(n-2)1_{2 \times 2} & 0_{2 \times 2} \\
0_{2 \times 2} & \cdots & 2(n-2)1_{2 \times 2} \\
0_{2 \times 2} & \cdots & (n-1)1_{2 \times 2} & 0_{2 \times 2}
\end{pmatrix}$$ (4.4)

Let $\mathcal{S}_m$ be the set of matrices in $\mathfrak{sl}_{2m}$ of the form

$$\begin{pmatrix}
y_1 & 1_{2 \times 2} \\
y_2 & 1_{2 \times 2} \\
\vdots & \ddots \\
y_{m-1} & 1_{2 \times 2} \\
y_m & 0_{2 \times 2}
\end{pmatrix}$$ (4.5)

Here $y_1 \in \mathfrak{sl}_2$ and $y_i \in \mathfrak{gl}_2$ for $i > 1$. It is easy to see that $\mathcal{S}_m$ is a homogeneous slice to the orbit of $x$ ([35], Lemma 23). $\chi$ restricted to $\text{Conf}^0_{2m}$ is a differentiable fiber bundle ([35], Lemma 20). We denote the fiber of $\chi$ over $t$ by $\mathcal{Y}_{m,t}$, i.e. $\mathcal{Y}_{m,t} = \chi^{-1}(t)$. If $t = (\mu_1, \ldots, \mu_{2m}) \notin \text{Conf}^0$, by $\mathcal{Y}_{m,t}$ we mean $\mathcal{Y}_{m,t'}$ where $t' = (\mu_1 - \sum \mu_i/2m, \ldots, \mu_{2m} - \sum \mu_i/2m)$. Let $E^\mu_y$ denote the $\mu$-eigenspace of $y$.

**Lemma 4.1.2** ([35], Lemmata 25 and 25). For any $y \in \mathcal{S}_m$ and $\mu \in \mathbb{C}$ the projection $\mathbb{C}^{2m} \rightarrow \mathbb{C}^2$ onto the first two coordinates gives an injective map $E^\mu_y \rightarrow \mathbb{C}^2$. Any eigenspace of any element $y \in \mathcal{S}_m$ has dimension at most two. Moreover the set of elements of $\mathcal{S}_m$ with 2 dimensional kernel can be canonically identified with $\mathcal{S}_{m-1}$ and this identification is compatible with $\chi$.

**Proof.** If the first claim is not true then the intersection of $E^\mu_y$ with $\{0\}^2 \times \mathbb{C}^{2m-2}$ is nonzero. Applying the $\mathbb{C}^*$ action we see that the same holds for $E^{r\mu}_{\lambda_r(y)}$. As $r$
goes to zero, $\lambda_r(y) \to x$ so we get $\dim \ker x > 2$ which is contradiction. From
this injectivity we see that each element of $\ker y$ is determined by its first two
coordinates so if $\dim \ker y = 2$ then $y_m = 0$ and vice versa. The subset of such
matrices is identified with $S_{m-1}$.

For a subset $A \subset \mathfrak{sl}_{2m}$, let $A^{\text{sub},\lambda}$ (resp. $A^{\text{sub},3,\lambda}$) be the subset of matrices in $A$
having eigenvalue $\lambda$ of multiplicity two (resp. three) and two Jordan blocks of size
one (resp. two Jordan blocks of sizes 1,2) corresponding to the eigenvalue $\lambda$ and
no other coincidences between the eigenvalues. Here are two results describing
neighborhoods of $S_{m}^{\text{sub},\lambda}$ and $S_{m}^{\text{sub},3,\lambda}$ in $S_{m}$.

**Lemma 4.1.3** ([35], Lemma 27). Let $D \subset \text{Conf}^0_{2m}$ be a disc consisting of the
2m-tuples $(\mu - \varepsilon, \mu - \varepsilon, \mu_3, \ldots, \mu_{2m})$ with $\varepsilon \in \mathbb{C}$ of small magnitude. Then there
is a neighborhood $U_{\mu}$ of $S_{m}^{\text{sub},\mu}$ in $S_{m} \cap \chi^{-1}(D)$ and an isomorphism $\phi$ of $U_{\mu}$ with
a neighborhood of $S_{m}^{\text{sub},\mu}$ in $S_{m}^{\text{sub},\mu} \times \mathbb{C}^3$ such that $f \circ \phi = \chi$ on $S_{m} \cap \chi^{-1}(D)$ where
$f(x, a, b, c) = a^2 + b^2 + c^2$. Also if $N_{y}S_{m}^{\text{sub},\mu}$ denotes the normal bundle to $S_{m}^{\text{sub},\mu}$
at $y$ the we have

$$\phi(N_{y}S_{m}^{\text{sub},\mu}) = \mathfrak{sl}(E_{y}^{\mu}) \oplus \zeta_{y}$$

where $\zeta_{y}$ is the trace free part of $\{C \cdot 1 \subset \mathfrak{gl}(E_{y}^{\mu})\} \oplus \mathfrak{gl}(E_{y}^{\mu_3}) \oplus \ldots \oplus \mathfrak{gl}(E_{y}^{\mu_{2m}})$.

**Proof.** For $y \in S_{m}^{\text{sub},\mu}$, let $S_{y}$ be a subspace of $T_{y}S_{m}$ complementary to $T_{y}S_{m}^{\text{sub},\lambda}$
which depends holomorphically on $y$. These subspaces together form a tubular
neighborhood of $S_{m}^{\text{sub},\mu}$ in $S_{m}$. Since $S_{m}$ and $\mathfrak{sl}_{2m}^{\text{sub},\mu}$ intersect transversely, $S_{y}$
is also a transverse slice at $y$ for the adjoint action on $\mathfrak{sl}_{2m}$. We can produce another
family of transverse slices $S_{y}'$ by setting $S_{y}' = \mathfrak{sl}(E_{y}^{\mu}) \oplus \zeta_{y}$ which equals the trace free
part of $\mathfrak{gl}(E_{y}^{\mu}) \oplus \mathfrak{gl}(E_{y}^{\mu_3}) \oplus \ldots \oplus \mathfrak{gl}(E_{y}^{\mu_{2m}})$. The reason is that $[y, \mathfrak{sl}_{2m}] = 0 \oplus \mathfrak{sl}_{2m-2}^{0}$
where the first component consists of zero in $\mathfrak{sl}_2$ and the second one consists of
matrices with zeros on the diagonal and the right hand side is transverse to $S_{y}'$.

Now $S_{y}$ is isomorphic (as an open complex manifolds) to $S_{y}'$ for each $y$ with an
isomorphism that moves points only inside their adjoint orbits (and hence is compatible with $\chi$). We can choose these isomorphisms to depend holomorphically
on \( y \). Each \( \mathfrak{gl}(E^\mu_y) \subset \mathfrak{sl}_{2m} \) for \( i > 2 \) can be canonically (without choice of a basis) identified with \( \mathbb{C} \). Lemma 4.1.2 tells us that \( E^\mu_y \) can be canonically identified with \( \mathbb{C}^2 \) so \( \mathfrak{sl}(E^\mu_y) \) is identified with \( \mathfrak{sl}_2 \). It follows that \( S'_y \cong \mathfrak{sl}_2 \otimes \mathbb{C}^{2m-2} \). The desired \( \phi \) is the composition of the two isomorphisms in this paragraph.

**Remark 4.1.4.** If \( y \) has two linearly independent \( \mu_1 \) eigenvectors as well as two linearly independent \( \mu_2 \) eigenvectors and with no other coincidences between the eigenvalues, we can repeat the above argument to obtain

\[
\phi(N_y(S^\text{sub,}\mu_1 \cap S^\text{sub,}\mu_2)) = \mathfrak{sl}(E^\mu_1) \oplus \mathfrak{sl}(E^\mu_2) \oplus \zeta. \tag{4.7}
\]

So \( \phi \) gives an isomorphism between a neighborhood of \( S^\text{sub,}\mu_1 \cap S^\text{sub,}\mu_2 \) in \( S_m \) and \((S^\text{sub,}\mu_1 \cap S^\text{sub,}\mu_2) \times \mathbb{C}^3 \times \mathbb{C}^3\).

Consider the line bundle \( \mathcal{F} \) on \( S^\text{sub,3,}\mu \) whose fiber at \( y \in S^\text{sub,3,}\mu \) is \( (y - m)E^\mu_y \) where \( y_s \) is the semisimple part of \( y \). To \( \mathcal{F} \) one associates a \( \mathbb{C}^4 \) bundle \( \mathcal{L} = (\mathcal{F}\setminus \emptyset) \times_{\mathbb{C}^*} \mathbb{C}^4 \) where \( z \in \mathbb{C}^* \) acts on \( \mathbb{C}^4 \) by

\[
(a, b, c, d) \rightarrow (a, z^{-2}b, z^2c, d). \tag{4.8}
\]

\( \mathcal{L} \) decomposes as

\[
\mathcal{L} \cong \mathbb{C} \oplus \mathcal{F}^{-2} \oplus \mathcal{F}^2 \oplus \mathbb{C}. \tag{4.9}
\]

Fibers of \( \mathcal{L} \) should be regarded as transverse slices in \( \mathfrak{sl}_3 \). Upon choosing suitable coordinates on such a transverse slice (at the zero matrix) the function \( \chi \) equals the function \( p : \mathfrak{sl}_3 \rightarrow \mathbb{C}^2 \) given by

\[
p(a, b, c, d) = (d, a^3 - ad + bc). \tag{4.10}
\]

\( p \) is also well-defined as a function \( \mathcal{L} \rightarrow \mathbb{C}^2 \) because \( b \) and \( c \) are coordinates on line bundles which are inverses of each other. Denote by \( \tau(d, z) \) the set of solutions of \( \lambda^3 - d\lambda + z = 0 \).

**Lemma 4.1.5** ([35], Lemma 28). Let \( P \subset \text{Conf}^{0}_{2m} \) be the set of \( 2m + 2 \)-tuples

\[
(\mu_1, \ldots, \mu_{i-1}, \tau(d, z), \mu_{i+3}, \ldots, \mu_{2m+2}). \tag{4.11}
\]
where $d$ and $z$ vary in a small disc in $\mathbb{C}$ containing the origin. There is a neighborhood $V$ of $S_m^{sl3}$ in $S_m \cap \chi^{-1}(P)$ and an isomorphism $\phi'$ from $V$ to a neighborhood of zero section in $\mathcal{L}$ such that $p(\phi'(x)) = (d, z)$ if

$$\chi(x) = (\mu_1, \ldots, \mu_{i-1}, \tau(d, z), \mu_{i+3}, \ldots, \mu_{2m+2}).$$

### 4.2 Relative vanishing cycles

Let $X$ be a complex manifold and $K$ a compact submanifold. Let $g$ be a Kähler metric on $Y = X \times \mathbb{C}^3$ (not necessarily the product metric) and denote its imaginary part by $\Omega$. Consider the map $f : X \times \mathbb{C}^3 \to \mathbb{C}$ given by $f(x, a, b, c) = a^2 + b^2 + c^2$ and denote by $\phi_t$ the gradient flow of $-\text{Re} \, f$. Let $W$ be the set of points $y \in Y$ for which the trajectory $\phi_t(y)$ exists for all positive $t$.

**Lemma 4.2.1.** $W$ is a manifold and the mapping $l : W \to X$ given by $l(y) = \lim_{t \to -\infty} \phi_t(y)$ is well-defined and smooth. We have $\Omega|_W = l^*\Omega|_X$. The function $f$ restricted to $W$ is real and nonnegative.

**Proof.** The first two assertions follow from stable manifold theorem (Theorem 1 in [8]) and the rest from the fact that gradient vector field of $-\text{Re} \, f$ is the Hamiltonian vector field of $\text{Im} \, f$. \qed

Set $V_t(K) = \pi^{-1}(t) \cap l^{-1}(K) = l|_{\pi^{-1}(t)}^{-1}(K)$ which is a manifold for $t$ small. It follows from Morse-Bott lemma that $V_t(K)$ is a 2-sphere bundle on $K$ for $t$ small. To generalize the invariant to tangles we will need a slightly more general version of the above construction in which $K$ is noncompact and the metric equals the product metric outside a compact subset. (See section 5.1.) The resulting vanishing cycle equals (symplectically) the product bundle outside a compact subset.
4.3 Fibered $A_2$ singularities

Assume we have the same situation as in the Lemma 4.1.5, i.e. let $\mathcal{F}$ be a holomorphic line bundle over a complex manifold $X$ and define $Y$ to be $(\mathcal{F}\setminus 0) \times_{\mathbb{C}^*} \mathbb{C}^4$ where the $\mathbb{C}^*$ action is as in the formula (4.8). Let $\Omega$ be an arbitrary Kähler form on $Y$ and by regarding $X$ as the zero section of $Y$, $\Omega$ restricts to a Kähler form on $X$. Let $(a, b, c, d)$ be the coordinates on fibers of $Y \to X$ and $(d, z)$ coordinates on $\mathbb{C}^2$. Let the map $p : Y \to \mathbb{C}^2$ be as in Lemma 4.1.5. Let $Y_d = p^{-1}(\mathbb{C} \times \{d\})$ and $p_d : Y_d \to \mathbb{C}$ be the restriction of $p$. Set $Y_{d,z} = p^{-1}(d, z)$. For $d \neq 0$ the critical values of $p_d$ are $\zeta_d^{\pm} = \pm 2\sqrt{d^3/27}$.

Let $K$ be Lagrangian submanifold of $X$. Using the relative vanishing cycle construction for the function $p_d$ we can obtain a Lagrangian submanifold $L_d$ of $Y$ which is a sphere bundle over $K$. (This construction works when $Y$ is a nontrivial bundle over $X$ as well.) There is another way of describing this Lagrangian as follows. Let $Y \cong \mathbb{C}^4$ be the fiber of $Y \to X$ over some point of $X$ and let $p : Y \to \mathbb{C}^2$ be as before. The restriction of the $\mathbb{C}^*$ action to $S^1$ is a Hamiltonian action with the moment map $\mu(a, b, c, d) = |c|^2 - |b|^2$. Define

$$C_{d,z,a} = \{(b, c) : \mu(b, c) = 0, a^3 - da - z = -bc\} \subset Y_{d,z}$$

(4.12)

which is a point if $a^3 - da - z = 0$ and a circle otherwise. The three solutions of this equation correspond to the critical values of the projection $q_{d,z} : Y_{d,z} \to \mathbb{C}$ to the $a$ plane. In the situation of Lemma 4.1.5 they correspond to the three eigenvalues of $Y$. Let $\alpha(r)$ be any embedded curve in $\mathbb{C}$ which intersects these critical values (only) if $r = 0, 1$. Define

$$\Lambda_\alpha = \bigcup_{r=0}^{1} C_{d,z,a(\alpha(r)}$$

(4.13)

which is a Lagrangian submanifold of $Y_{d,z}$ (with Kähler form induced from $\mathbb{C}^4$). Let $c, c', c''$ be as in the Figure 4.1 where dots represent the critical values of $q_{d,z}$. We can associate to $K$ a Lagrangian submanifold $\Lambda_{d,\alpha}$ of $Y$ by defining
\[ \Lambda_{d,\alpha} = (Y|K) \times S^1 \Lambda_c. \] Seidel and Smith prove that these two procedures give the same result ([35], Lemma 40):

**Lemma 4.3.1.** If the Kähler form on \( Y \) is obtained from a Kähler form on \( X \), a Hermitian metric on \( F \) and the standard form on \( \mathbb{C}^4 \) then \( L_d = \Lambda_{d,c} \).

\[ \begin{tikzpicture}
    \begin{scope}[rotate=-90]
        \node (a) at (0,0) {}; 
        \node (b) at (1,0) {}; 
        \node (c) at (2,0) {}; 
        \node (d) at (3,0) {}; 
        \node (e) at (4,0) {}; 
        \draw[black,loosely dashed] (a) to (b) to (c) to (d) to (e); 
        \draw[black] (a) to (d); 
    \end{scope}
\end{tikzpicture} \]

**Figure 4.1:**

### 4.4 Symplectic structure

The symplectic structure that Seidel and Smith use on \( S_m \) is not the standard structure on \( S_m \cong \mathbb{C}^{4m-1} \). This is to obtain well-defined parallel transport maps for the fibration \( \chi \) whose fibers are noncompact. We need a plurisubharmonic function whose fiberwise critical point sets project properly under \( \chi \). Fix \( \alpha > m \). Let \( \xi_i(z) = |z|^{2\alpha/i} \) for \( z \in \mathbb{C} \) and \( i = 1, \ldots m \). These functions are only \( C^1 \) but by adding compactly supported functions \( \eta_i \) we can obtain \( C^\infty \) functions \( \psi_i = \xi_i + \eta_i \) on \( \mathbb{C} \). We choose \( \eta_i \) such that \(-dd^c \psi_i > 0\). Let \( \psi \) be the function on \( S_m \) whose value at \( y \in S_m \) is

\[
\sum_{i=1}^{m} \sum_{\mu,\nu \in \{0,1\}} \psi_i((y_i)_{\mu,\nu}).
\]

Here the \( y_i \) are the components of \( y \) as in (4.5). We can choose \( \eta_i \) so that \( \psi \) is an exhausting plurisubharmonic function on \( S_m \) which gives us the symplectic form \( \Omega = -dd^c \psi \). Outside a set which is the product of the complement of a compact set in each coordinate plane, we have

\[
\Omega = 4 \sum_{i=1}^{m} (\alpha/i)(\alpha/i - 1) \sum_{\mu,\nu \in \{0,1\}} |(y_{1i})_{\mu,\nu}|^{2\alpha/i} d((y_{1i})_{\mu,\nu}) \wedge d\overline{(y_{1i})_{\mu,\nu}}.
\]
By restriction we obtain Stein structures on each $\mathcal{Y}_{m,t}$. The addition of the functions $\eta_i$ prevents $\psi$ from being homogeneous with respect to the $\lambda_r$ action but as $r \to \infty$ the functions $\eta_i(r^i z)$ are supported on smaller and smaller neighborhood of origin so $\eta_i(r^i z)/r^{2\alpha}$ go to zero and so we get the asymptotic homogeneity of $\psi$, i.e.:

$$\lim_{r \to \infty} \frac{\psi \circ \lambda_r}{r^{2\alpha}} = \xi. \quad (4.14)$$

Since the fibers $\mathcal{Y}_{m,t}$ are noncompact, existence of parallel transport maps for the fiber bundle $\chi|_{\text{Conf}_2^0}$ is not guaranteed. Let $\beta$ be a curve in $\text{Conf}_{2m}$. Let $H_\beta$ be the horizontal lift of $\dot{\beta}$ and $Z_\beta(s)$ be the projection of $\nabla \psi(\beta(s))$ to $\mathcal{Y}_{m,\gamma(s)}$. Seidel and Smith obtain a rescaled parallel transport map $h_{\beta}^{res}: \mathcal{Y}_{m,\beta(0)} \to \mathcal{Y}_{m,\beta(1)}$ which is given by integrating the vector field

$$H_\beta - \sigma Z_\beta \quad (4.15)$$

and then composing by the time $\sigma$ map of $Z_\beta(1)$, where $\sigma$ is a positive constant (depending on $\beta$). The map $h_{\beta}^{res}$ is a symplectomorphism defined on arbitrarily large compact subsets of $\mathcal{Y}_{m,\beta(0)}$. For this procedure to work, one needs the fiberwise critical point set of $\psi$ to project properly under $\chi$. The homogeneity property (4.14) ensures this. See [35] Section 5A.

If $\mu \in \mathbb{C}^{2m}/S_{2m}$ has only one element of multiplicity two or higher, which we denote by $\mu_1$, denote by $\mathcal{D}_{m,\mu}$ the set of singular elements of $(\chi^{-1}(\mu) \cap S_m)$ i.e.

$$\mathcal{D}_{m,\mu} = (\chi^{-1}(\mu) \cap S_m)^{\text{sub},\mu_1}. \quad (4.16)$$

Let $\mathcal{D}_{m}$ be the union of all these $\mathcal{D}_{m,t}$ regarded as a subset of $S_m$. It inherits a Kähler metric from $S_m$. We have the map $\chi: \mathcal{D}_m \to \mathbb{C} \times \mathbb{C}^{2m-2}/S_{2m-2}$. By forgetting the first eigenvalue, the image of $\chi$ can be identified with $\text{Conf}_{2m-2}$. Lemma 4.1.2 tells us that if $\mu_1 = 0$ then $\mathcal{D}_{m,\mu}$ can be identified with $\mathcal{Y}_{m-1,\mu}\backslash\{\mu_1\}$. It can be shown ([35] Section 5A) that $\chi$ is a differentiable fiber bundle and we have rescaled parallel transport maps

$$h_{\beta}^{res}: \mathcal{D}_{m,\beta(0)} \to \mathcal{D}_{m,\beta(1)} \quad (4.17)$$
for any curve $\beta$ in $\text{Conf}_{2m-2}$. These parallel transport maps are compatible with those for $\mathcal{Y}_{m-1,\mu\setminus\{0\}}$ under the identification above provided that $\beta$ lies in $\text{Conf}^0_{2m-2}$. This is because of the special (product) form of the symplectic structure.

4.5 Lagrangian submanifolds from crossingless matchings

Let $\mu \in \text{Conf}_{2m}$. A crossingless matching $D$ with endpoints in $\mu$ is a set of $m$ disjoint embedded curves $\delta_1, \ldots, \delta_m$ in $\mathbb{C}$ which have (only) elements of $\mu$ as endpoints. See Figure 4.2. To $D$ we associate a Lagrangian submanifold $L_D$ of $\mathcal{Y}_{m,\mu}$ as follows. Let $\{\mu_{2k-1}, \mu_{2k}\} \subset \mu$ be the endpoints of $\delta_k$ for each $k$. Let $\gamma$ be a curve in $\text{Conf}^0_{2m}$ such that $\gamma(t) = \{\gamma_1(t), \gamma_2(t), \mu_3, \mu_4, \ldots, \mu_{2m}\}$, $\gamma_i(0) = \mu_i, i = 1, 2$ and as $s \to 1$, $\gamma_1(t), \gamma_2(t)$ approach each other on $\delta_1$ and collide. For example if $\delta_1(t)$ is a parametrization of $\delta_1$ s.t. $\delta_1(0) = \mu_1, \delta_1(1) = \mu_2$ the we can take $\gamma(t) = \{\delta(t/2), \delta(1-t/2), \mu_3, \ldots, \mu_{2m}\}$. Set $\bar{\mu} = \mu \setminus \{\mu_1, \mu_2\}, \mu' = \gamma(1)$.

If $m = 1$ then relative vanishing cycle construction for $\chi : S_1 \to \mathbb{C}$ with the critical point over $\gamma(1) = 0$ gives us a Lagrangian sphere $L$ in $\mathcal{Y}_{1,\gamma(1-s)}$ for small $s$. Using reverse parallel transport along $\gamma$ we can move $L$ to $\mathcal{Y}_{1,\mu}$ to get our desired Lagrangian submanifold. Now for arbitrary $m$ assume by induction that we have obtained a Lagrangian $L_{\bar{D}} \subset \mathcal{Y}_{m-1,\bar{\mu}}$ for $\bar{D}$ which is obtained from $D$ by deleting $\delta_1$. Now $\mathcal{Y}_{m-1,\bar{\mu}}$ can be identified with $D_{m,\tau}$ where $\tau = (0, 0, \mu_3 - (\mu_1 + \mu_2)/(2m-2), \ldots, \mu_{2m} - (\mu_1 + \mu_2)/(2m-2))$. Use parallel transport to move $L_{\bar{D}}$ to $D_{m,\gamma(1)}$. The later one is the set of singular points of $\mathcal{Y}_{m,\gamma(1)}$ so Lemma 4.1.3 tells us that we can use relative vanishing cycle construction for $L_{\bar{D}}$ to obtain a Lagrangian in $\mathcal{Y}_{m,\gamma(1-s)}$ for small $s$. Parallel transporting it along $\gamma$ back to $\mathcal{Y}_{m,\mu}$ we obtain our desired Lagrangian which is topologically a trivial sphere bundle on $L_{\bar{D}}$. We see that $L_D$ is diffeomorphic to a product of spheres. Different choices of the curve $\gamma$ result in Hamiltonian isotopic Lagrangians. The same holds if we isotope the curves in $D$ inside $\mathbb{C}\setminus\mu$. 
4.6 The Seidel-Smith invariant

Now we can define the Seidel-Smith invariant. Since each manifold $\mathcal{Y}_{m,\nu}$ is a submanifold of the affine space $\mathcal{S}_m$ and has trivial normal bundle, its Chern classes are zero. This together with the fact that $H_1(\mathcal{Y}_m) = 0$ implies that the canonical bundle of $\mathcal{Y}_{m,\nu}$ is trivial and so has a unique infinite Maslov cover. We start by choosing global sections $\eta_{\mathcal{S}_m}$ and $\eta_{h/W}$. Then we choose trivializations for regular fibers of $\chi_{\mathcal{S}_m}$ characterized by $\eta_{\mathcal{Y}_{m,t}} \wedge \chi^* \eta_{h/W} = \eta_{\mathcal{S}_m}$. If we choose a grading for $L \subset \mathcal{Y}_{m,0}$ and $\beta$ is a curve in $\text{Conf}_{2m}$ starting at $t_0$, one can continue the grading on $L$ uniquely to $h_{\beta|[0,s]}(L)$ for any $s$. Therefore the grading of $L$ uniquely determines that of $h_{\beta}(L)$.

Let $\mathcal{D}_+$ be the crossingless matching at the left hand side of picture 4.2. If a link $K$ is obtained as closure of a braid $\beta \in \text{Br}_m$, let $\beta' \in \text{Conf}_{2m}$ be the braid obtained from $\beta$ by adjoining the identity braid $\text{id}_m$.

**Definition 4.6.1.**

$$\mathcal{HSS}^*(K) = HF^{r+m+w}(L_{\mathcal{D}_+}, h_{\beta'}(L_{\mathcal{D}_+}))$$

Here $w$ is the writhe of the braid presentation, i.e. the number of positive crossings minus the number of the negative crossings in the presentation. Since the manifold is convex at infinity and the Lagrangians are exact, the above Floer cohomology is well-defined. Independence from choice of $\beta$ is proved in [35], section 5C. Well-definedness of the invariant developed in this thesis gives an alternative proof. See Theorem 5.1.8.
Chapter 5

Generalization to tangles

In this Chapter we generalize the invariant of Seidel and Smith to tangles. This material can be found in [29] as well.

5.1 The functor associated to a tangle

Let

\[ n_0 T_1 n_1 T_2 \ldots n_{l-1} T_l n_l \]

be a decomposition of an oriented tangle \( T \) into elementary tangles. Set \( \nu_j = i(T_j) \) and \( \nu_{l+1} = t(T_l) \). We have \( \nu_i \in \text{Conf}_{n_i} \) for \( i = 0, \ldots, l \). To each \( T_i \) we want to associate a Lagrangian correspondence \( L_{i,i+1} = L_{T_i} \) between \( Y_{n_i, \nu_i} \) and \( Y_{n_{i+1}, \nu_{i+1}} \).

In this way we can associate to \( T \) a generalized Lagrangian correspondence

\[ \Phi(T) = (L_{0,1}, L_{1,2}, \ldots, L_{n-1,n}) \{-m - w\} \]

from \( Y_n \) to \( Y_m \). Here \( m \) and \( w \) are the number of cups and the writhe (number of positive crossings minus the number of negative ones) of the decomposition respectively.

If \( T_k \) is an elementary braid in \( Br_{2m} \), we set \( L_{T_k} \) to be \( \text{graph}(h_{\beta}^{res}) \) regardless of the orientation of the braid. Of course we can extend this definition to any braid. We note that the symplectomorphisms \( h_{\beta}^{res} \) are defined only on compact submanifols of the \( Y_m \), however this does not cause any problem since we are going to take the \( \mathcal{C}_c \) of these Lagrangians. We will make use of an alternative description of these symplectomorphisms as Dehn twists around vanishing cycles.
This description is not indispensable for our purpose but makes the presentation simpler. Let $V_i$ be the relative vanishing cycle for the map $f$ in Lemma 4.1.3 where $i$th and $(i+1)$th eigenvalues $(\mu_i, \mu_{i+1})$ of $\nu_k$ come together at some point $\mu$.

There is a theorem of T. Perutz (generalizing an earlier result of P. Seidel) which describes monodromy maps around singularities of symplectic Morse-Bott fibrations as Dehn twists. Recall that a symplectic Morse-Bott fibration (also called Lefschetz-Bott fibrations) over a disc $D$ consists of an almost complex manifold $(E, J)$, a closed two-form $\Omega$ on $E$ and a $J$-holomorphic map $\pi : E \to D$ such that the critical point set of $\pi$ is a submanifold of $E$ and the complex Hessian matrix of $\pi$ is nondegenerate. The form $\Omega$ is required to be a symplectic form when restricted to each fiber.

**Theorem 5.1.1** (Perutz [27], Theorem 2.19). Let $\pi : E \to D$ be a symplectic Morse-Bott fibration over the closed disc $D$ which has only the origin as singular value. If in addition the fibration is normally Kähler, i.e. a neighborhood of the critical point set of $\pi$ is foliated by $J$-complex normal slices such that $J$ restricted to each slice is integrable and the restriction of $\Omega$ to each fiber is Kähler, then the monodromy map around the origin is Hamiltonian isotopic to the fibred Dehn twist $\tau_V$ along the vanishing cycle $V$ for the map $\pi$.

Therefore using the local picture of the Lemma 4.1.3 we see that if we have a subset $B \subset \mathcal{Y}_m$ for which the naive (non-rescaled) parallel transport map $h_{\sigma_i}|_B$ is well-defined then

$$h_{\sigma_i} \cong \tau_{V_i}. \quad (5.3)$$

The reason is that since the naive parallel transport is well-defined for all points of $B$, we can shrink the rescaling parameter in (4.15) to zero and thereby isotope $h^{res}_{\sigma_i}$ to $h_{\sigma_i}$.

**Lemma 5.1.2.** Let $\nu = \{\mu_1, \ldots, \mu_{2m}\} \in \text{Conf}_{2m}^0$ and $\gamma : [0, 1] \to \mathfrak{h}/W$ such that $\gamma(0) = \nu$ and as $s \to 1$, $\mu_{2i-1}$ and $\mu_{2i}$ approach each other linearly and collide at
some $\mu$. Then $h_{\sigma_i}^{res}$ restricted to $S_m^{sub,\mu}$ is the identity. Similarly if $\mu_{2k-1}, \mu_{2k}, \mu_{2k+1}$ come together at some $\mu$, then $\sigma_i$ and $\sigma_{i+1}$ act trivially on $S_m^{sub,3,\mu}$.

Proof. We use the picture of Lemma 4.1.5. Both statements follow from (7.32) and the fact that fibred Dehn twists are identity outside a small neighborhood of the spherical fibres. \hfill \Box

Let $V_{ix}$ denote the ($S^2$) fiber of $V_i$ over $x$. We grade $\tau_{V_i}$ in such a way that

$$\tau_{V_i} V_{ix} = V_{ix} \{1\}$$

and the grading function vanishes outside a neighborhood of $V_i$. This grading is unique. (Lemma 5.6 in \cite{32})

**Remark 5.1.3.** Monodromy actions of braid group on symplectic manifolds were first constructed in \cite{16}. Parallel transport maps $h_{\beta}^{res}$ form a homomorphism from $\pi_1(Conf_{2m}) = Br_{2m}$ into the $\pi_0$ of $Symp(\mathcal{Y}_m)$. In particular symplectomorphisms associated to elementary braids satisfy Artin’s commutation relations. (Symplectic manifolds used in \cite{16} are compact with boundary. The manifolds $\mathcal{Y}_m$ in \cite{35} that we use here can be obtained from them by attaching an infinite cylinder.)

If $T_i = \cup_{j,m}$, we define a Lagrangian $L_{\cup_{j,m}}$, regardless of the orientation of $\cup_{k,m}$, as follows. The result depends on a real parameter $R > 0$. To simplify the notation we set $k = j, l = j+1$. With $\nu_i$ as given above let $\nu = \nu_i = \{\mu_1, \ldots, \mu_{2m}\}$. Let $\gamma$ be a curve in $Conf^0_{2m}$ such that $\gamma(0) = \nu_i$ and as $s \to 1$, $\mu_k$ and $\mu_l$ approach each other linearly and collide at a point $\mu'$. For example we can take

$$\gamma(t) = \{\mu_1, \ldots, \mu_k + t(\mu_l - \mu_k)/2, \ldots, \mu_l - t(\mu_l - \mu_k)/2, \ldots, \mu_{2m}\}$$

provided that $\mu_k + t(\mu_l - \mu_k)/2$ does not intersect the other $\mu_i$. Set $\nu^{k,l} = \nu \setminus \{\mu_k, \mu_l\}$, $\nu' = \gamma(1)$. We use Lemma 4.1.3 to identify a neighborhood of $S_m^{sub,\mu'}$ in $S_m$ locally with $S_m^{sub,\mu'} \times \mathbb{C}^3$. This induces a Kähler form and hence a metric on $S_m^{sub,\mu'} \times \mathbb{C}^3$. We perturb the complex structure outside a compact ball of radius $\rho$ (to be chosen below) so that outside that set the resulting metric equals the product metric. Now we use the relative vanishing cycle
construction for the whole $S_{m}^{\nu_{b},\mu'}$. It yields (after restriction) a sphere bundle \( V = V_{\gamma(1-s)}(S_{m}^{\nu_{b},\mu'}) \subset Y_{m,\gamma(1-s)} \) for small \( s \) with projection \( \pi : V \to \mathcal{Y}_{m,\nu'} \cap S_{m}^{\nu_{b},\mu'} \). The relative vanishing cycle construction can be used because the metric equals the product metric outside a compact set.

We denote the image of \( V \) under parallel transport map along \(-\gamma\), i.e.

\[
h_{\gamma}^{-1}(V) \subset \mathcal{Y}_{m,\nu}
\]

by the same notation \( V \). Composing \( \pi \) with the parallel transport map \( h_{\gamma}^{-1} \) we obtain a projection \( \pi : V \to \mathcal{Y}_{m,\nu'} \cap S_{m}^{\nu_{b},\mu'} \) which is an \( S^{2} \) bundle. By Lemma 4.1.3, \( \mathcal{Y}_{m,\nu'} \cap S_{m}^{\nu_{b},\mu'} \) can be identified with \( \mathcal{D}_{m-1,\nu'} \) from (4.16). Let \( \delta \) be a geodesic in \( \text{Conf}^{S} \) joining \( \nu' \) to \( \nu^{k,l} \). We can use parallel transport map (4.17) along the curve \( \delta \) to map \( \mathcal{D}_{m-1,\nu'} \) to \( \mathcal{D}_{m-1,\nu^{k,l}} \cup \{0,0\} \). The latter can be identified with \( \mathcal{Y}_{m-1,\nu^{k,l}} \). So we obtain a fibration \( \pi : V \to \mathcal{Y}_{m-1,\nu^{k,l}}. \) We can use this map \( \pi \) to pull \( V \) back to \( \mathcal{Y}_{m-1,\nu^{k,l}} \times \mathcal{Y}_{m-1,\nu^{k,l}} \). Let \( \cup_{j;m} \) be its restriction to the diagonal. It is a Lagrangian submanifold of \( \mathcal{Y}_{m,\nu_{i}} \times \mathcal{Y}_{m-1,\nu^{k,l}} = \mathcal{Y}_{m,\nu_{i}} \times \mathcal{Y}_{m-1,\nu^{k,l}}. \) Let \( \psi = \psi_{1} + \psi_{2} \) be the plurisubharmonic function on \( \mathcal{Y}_{m,\nu_{i}} \times \mathcal{Y}_{m-1,\nu^{k,l}}. \) We can choose \( \rho \) in such a way that the inverse image of \( \psi = R \) lies inside the ball of radius \( \rho \). We have a projection \( \pi : L_{\cup_{j;m}} \to \Delta \subset \mathcal{Y}_{m,\nu_{i+1}} \times \mathcal{Y}_{m-1,\nu^{k,l}}. \)

As in the case of Lagrangians from crossingless matchings, replacing the curve \( \gamma \) with another curve in the same homotopy class (with fixed endpoints) results in a new \( L_{\cup_{j;m}} \) which is Lagrangian isotopic to the former one. Since the first homology group of this Lagrangian is zero, this isotopy is exact.

We grade the \( L_{\cup_{j}} \) as follows. Lemma 5.1.7 below tells us that fibers of \( L_{\cup_{j}} \) and \( L_{\cup_{j+1}} \) over each point of the diagonal intersect transversely at only one point. We choose the grading in such a way that the absolute Maslov index of this intersection point (with regard to the two \( S^{2} \) fibres) equals one. We can use Lemma 4.1.3 and isotope \( L_{\cup_{j}} \) to \( \Delta \times \sqrt{z}S^{2} \) for some small \( z \in \mathbb{C} \). For any two Lagrangians \( L, L' \) we have \( \alpha_{L \times L'} = \alpha_{L} \times \alpha_{L'} \). Also the two form \( \eta_{r \times s^{2}} \) when
restricted to $S^2$ is a volume form on $S^2$. Therefore we get $\alpha_{L^c} = \alpha_\Delta \cdot \frac{\dot{z}}{|z|}$. The function $\alpha_\Delta$ is constant. This means that the grading on $L_{\cap_j}$ is determined by the choice of a branch of arg$(z)$. In particular such a grading is a constant function:

$$L_{\cup_j} = c_j.$$  \hspace{1cm} (5.5)

We choose this $c_j$ to be the same for every $j$. This together with the formula (2.12) (for $n = 2$) imply that the absolute Maslov index of each fiberwise intersection point in $L_{\cup_j} \cap L_{\cup_{j+1}}$ equals 1. Construction for $\cap_j$ is similar.

The following lemma insures that the Lagrangian we assign to crossingless matching agrees with that of Seidel and Smith.

**Lemma 5.1.4.** If $C \in \mathcal{C}_m$ is a crossingless matching and arcs of $C$ are isotopic to $T_1, T_2, \ldots, T_m$ where each $T_i$ is either a cap or a cup then $L_C$ is isotopic to $L_{T_1} \circ \cdots \circ L_{T_m}$.

**Proof.** We use induction on $m$. The base case is vacuous. For the induction step we note that our construction is the same as the induction step in the construction of Seidel and Smith (Section 4.5 above) except for the base of the fibration. \hspace{1cm} $\square$

In order for $\Phi$ to define a functor, we must verify that the above correspondences satisfy the same commutation relations as the tangles they are associated to. First we have the following cf. Remark 5.1.3.

**Lemma 5.1.5.** We have $L_{\sigma_i}L_{\sigma_{i+1}}L_{\sigma_i} = L_{\sigma_{i+1}}L_{\sigma_i}L_{\sigma_{i+1}}$ and if $|i - j| > 1$, $L_{\sigma_i}L_{\sigma_j} = L_{\sigma_j}L_{\sigma_i}$.

**Lemma 5.1.6.** We have

$$L_{\cap_i}L_{\sigma_j} \simeq L_{\sigma_j}L_{\cap_i}, \hspace{1cm} L_{\cup_i}L_{\sigma_j} \simeq L_{\sigma_j}L_{\cup_i}$$  \hspace{1cm} (5.6)
if $|i - j| > 1$ and for any $i$ we have:

\[
L_{\cap} L_i \simeq L_{\cap} \{1\} \quad L_{\sigma_i} L_{\cup_i} \simeq L_{\cup_i} \{1\} \tag{5.7}
\]

\[
L_{\sigma_i} L_{\cup_{i+1}} \simeq L_{\sigma_{i+1}}^i L_{\cup_i} \quad L_{\sigma_{i+1}} L_{\cup_i} \simeq L_{\sigma_i}^i L_{\cup_{i+1}} \tag{5.8}
\]

where \( \simeq \) means exact isotopy.

Proof. Let \( \beta : [0, 1] \to \text{Conf}_{2m}^0 \) be a braid such that \( \beta(0) = \beta(1) = \nu \). Note that in the construction of \( L_{\cap} \) if we replace the curve \( \gamma \) with \( \beta \ast \gamma \) and also replace \( \delta \) with \( \delta \ast \alpha \) where \( \alpha \) joins \( \nu^{(k)} \) to \( \nu \setminus \{ \beta(2k - 1), \beta(2k) \} \), the construction will yield \( h_\beta(\cap_{k:m}) \). In general the basepoint \( \nu^{(k)} \) or \( \nu \setminus \{ \beta(2k - 1), \beta(2k) \} \) is of no importance so we can assume \( \alpha \) to be constant. If \( \beta \) equals \( \sigma_k \) then \( \beta \ast \gamma \) joins \( \mu_{2k-1}, \mu_{2k} \) and fixes the other eigenvalues so the construction will yield the same \( L_{\cap_k} \). If \( \beta = \sigma_{k+1} \) then \( \beta \ast \gamma \) the result will be the same as starting with \( \cap_{i+1} \) and using \( \beta = \sigma_k \). These two facts imply the above isotopies ignoring grading.

As another proof which shows equality of graded Lagrangians, we appeal to (5.4) which implies (5.7). To prove (5.8), we use Lemma 5.8 in [32] which asserts if \( L_0, L_1 \) are two graded Lagrangian spheres whose intersection consists of only one point of Maslov index one and with the grading of the Dehn twists and chosen as above, we have

\[
\tau_{L_0} L_1 = \tau_{L_0}^{-1} L_0 \tag{5.9}
\]

as graded Lagrangians. Now we use Lemma 4.1.5 to translate the picture into that of section 4.3. So we can identify \( L_{\cup_i} \) with \( \Lambda_{\alpha_1} \times S^1 \Delta \) and \( L_{\cup_{i+1}} \) with \( \Lambda_{\alpha_2} \times S^1 \Delta \).

Because \( h_{\sigma_i} \) and \( h_{\sigma_{i+1}} \) act trivially on \( \Delta \) by 5.1.2, we can identify them with Dehn twists around \( \Lambda_{\alpha_1} \) and \( \Lambda_{\alpha_2} \) respectively. Our choice of grading (5.5) for \( L_{\cup_i} \) implies that the hypothesis of (5.9) are met. This immediately implies (5.8).

Note that because \( \Lambda_{\alpha_i} \) are two dimensional, changing the order of them does not change the Maslov index of the intersection point. \( \square \)

**Lemma 5.1.7.** We have the following commutation relations where \( \simeq \) means exact isotopy.
\[ L_{\cap} \cap_{\cup} \simeq L_{\cup} \cup_{\cap} \quad \text{if} \quad |i - j| > 1. \quad (5.10) \]

\[ L_{\cap_{\cup},m} L_{\cup_{\cap},i+1,m} \simeq L_{\cap,1} \{1\} \quad \text{for any} \quad i. \quad (5.11) \]

**Proof.** To prove (5.10) let \( \nu = \{ \mu_1, ..., \mu_{2m} \} \) and \( \nu', \nu'', \nu''' \) be \( \nu \) minus \( \{ \mu_{2i-1}, \mu_{2i} \}, \{ \mu_{2j-1}, \mu_{2j} \} \) and \( \{ \mu_{2i-1}, \mu_{2i}, \mu_{2j-1}, \mu_{2j} \} \) respectively. Therefore

\[ L_{\cap_{\cup},m} \subset Y_{m-1,\nu'} \times Y_{m,\nu} \quad \text{and} \quad L_{\cup_{\cap},m} \subset Y_{m,\nu} \times Y_{m-1,\nu''}. \]

We have projections \( \pi_i : L_{\cap_{\cup},m} \to Y_{m-1,\nu'}, \pi_j : L_{\cup_{\cap},m} \to Y_{m-1,\nu'} \) given in the construction of these Lagrangians. We have

\[
L_{\cap_{\cup},m} L_{\cup_{\cap},m} = \{(m_1, m_2) | \exists m', (m_1, m') \in L_{\cap_{\cup},m}, (m', m_2) \in L_{\cup_{\cap},m} \} \\
= \{(m_1, m_2) | \exists m', m_1 = \pi_i(m'), m_2 = \pi_j(m') \}.
\]

\[
L_{\cup_{\cap},m} L_{\cap_{\cup},m} = \{(m_1, m_2) | \exists m', (m_1, m') \in L_{\cup_{\cap},m}, (m', m_2) \in L_{\cap_{\cup},m} \} \\
= \{(m_1, m_2) | \exists m', \pi_j(m_1) = m', \pi_i(m_2) = m' \} \\
= \{(m_1, m_2) | \pi_j(m_1) = \pi_i(m_2) \}
\]

By the remark after the Lemma 4.1.3, these projections are given by projection to the first and second factor in \( \mathfrak{sl}(E_{\mu_1}) \oplus \mathfrak{sl}(E_{\mu_2}) \oplus \zeta \) and so \( \pi_i \pi_j = \pi_j \pi_i \) from which the equality of the compositions follows.

As for (5.11) we must show that \( L_{\cap_{\cup}} \circ L_{\cup_{\cap}} \) equals the diagonal \( \Delta \subset Y_m \times Y_m \). Using Lemma 5.1.6 we see that

\[ h_{\sigma_i, \sigma_{i+1}} L_{\cap_{\cup}} = L_{\cap_{\cup}}. \]

So we are reduced to showing that \( L_{\cap_{\cup}} \cap h_{\sigma_i, \sigma_{i+1}}(L_{\cap_{\cup}}) \simeq \Delta \). Let \( \nu = (\mu_1, ..., \mu_{2m+2}) \) be such that \( \mu_i + \mu_{i+1} + \mu_{i+2} = 0 \). Also denote \( \tilde{\nu} = (\mu_1, ..., \mu_{i-1}, 0, 0, \mu_{i+3}, ..., \mu_{2m+2}) \) and

\[ \tilde{\nu} = (\mu_1, ..., \mu_{i-1}, 0, 0, \mu_{i+3}, ..., \mu_{2m+2}). \]
We take $Y_{m+1} = Y_{m+1,\nu}$ and $Y_m = Y_{m,\nu}$. The latter can be identified with $D_{m+1,\nu}$ which is $(\chi^{-1}(\nu) \cap S_{m+1})_{s\mu = 0}$. Lemma 4.1.5 gives us a $\mathbb{C}^4$-bundle $L$ over $S_{m+1}^{s\mu = 0}$ with a local symplectomorphism $\phi$ from $L$ to a neighborhood $U$ of $S_{m+1}^{s\mu = 0}$ in $S_{m+1}$.

We identify $Y_{m+1,\nu}$ with its image under $\phi$ and so $\Delta \subset L \times S_{m+1}^{s\mu = 0,\nu}$ lies in the zero section and $L \cap \Delta$ is the pullback of a sphere bundle over the zero section to $\Delta$. Lemma 4.1.5 gives us a $C_4$-bundle $L$ over $S_{m+1}^{s\mu = 0,\nu}$ with a local symplectomorphism $\phi$ from $L$ to a neighborhood $U$ of $S_{m+1}^{s\mu = 0}$ in $S_{m+1}$.

Let $L_1$ and $L_2$ be fibers of $L_{\cap}$ and $h_{\sigma_1,\sigma_2}(L_{\cap})$ over a point of $\Delta$. So

$$L_2 = h_{\sigma_1,\sigma_2}(L_1). \tag{5.12}$$

By Lemma 4.3.1, $L_{\cap}$ is isotopic to $\Lambda_{d,\alpha_1} = \Delta \times S_1 \Lambda_\alpha$ so $L_1$ can be identified with $\Lambda_{\alpha_1}$. When we perform $h_{\sigma_1,\sigma_2}$, the leftmost and the rightmost zeros in Figure 4.1 (which are the “fiberwise” eigenvalues) get swapped; therefore $c$ is sent to $c'$ and so $L_2 = \Lambda_c$. Since $\Lambda_c = \bigcup_{r=0}^1 C_{d,z,c(r)}$ and $C_{d,z,a}$ is given by $C_{d,z,a} = \{(b,c) : |b| = |c|, a^3 - da - z = -bc\}$, we see that since the curves $c$ and $c''$ intersect at only one point (i.e. the first root of $a^3 - ad - z = 0$) then $L_1 = \Lambda_{\alpha_1}$ and $L_2 = \Lambda_{\alpha_2}$ intersect at only one point so the proof is complete.

We chose the gradings (5.5) for $L_{\cap}$ to be a constant function $c$ and be the same for all $i$. Let $S_{ix}$ be the fiber of $L_{\cap}$ over $x$. Then the fiber of $L_{\cap} \circ L_{\cup \cap +1,m}$ over $x$ equals $S_{ix} \circ S_{i+1,x}^t$. The grading of $S_{i+1,x}^t$ equals $1 - \tilde{S}_{i+1,x}$ by (2.16). Therefore the grading of the point $S_{ix} \circ S_{i+1,x}^t$ is $c + 1 - c = 1$ which implies (5.11).

\[\square\]

Theorem 5.1.8. The assignment $\Phi$ in (5.2) is a functor from the category of even tangles to the symplectic category.
Proof. Follows from 3.1.4 and 5.1.5 to 5.1.7. We see that difference in grading for each commutation relation gets canceled by the change in the writhe plus number of cups. The only commutation relations which involve grading shift are (5.7) and (5.11) which happen to be the only ones involving change in $-m - w$. For (5.11), $-m$ plus the degree shift is equal on both sides of the equation. Note that if $T$ contains $\cap_i (\sigma_i^\epsilon)^\pm$ where $\epsilon = 1, -1$ and $\pm$ is the writhe of $\sigma_i$ then $\pm \epsilon$ has to be equal to $-1$. This implies that $-w$ plus the grading shift is equal on both sides of (5.7).

Remark 5.1.9. The functor $\Phi$ can be viewed as a (graded) genus zero symplectic valued topological field theory which is defined only for even tangles.

5.2 The group valued invariant

We can obtain tangle invariants at two levels from the symplectic valued topological field theory $\Phi$: a functor valued invariant and a group valued one. The functor valued invariant is discussed in 6. The group valued tangle invariant is defined as follows.

Definition 5.2.1.

\[ HSS(T) = \bigoplus_{\substack{C \in C_m \\ C' \in C_n}} HF(L_C^l, \Phi(T), L_{C'}) \]  
\[ CSS(T) = \bigoplus_{\substack{C \in C_m \\ C' \in C_n}} CF(L_C^l, \Phi(T), L_{C'}) \]  

We will, in section 7.5, put extra conditions on the chain complex (5.14) for $T$ a flat tangle. Each summand in the above direct sum is equal to the Floer cohomology of the Lagrangians

\[ \mathcal{L}_0 = L_C \times L_0 \times L_{1,2} \times \ldots \times L_{2k-1,2k} \]
\[ \mathcal{L}_1 = L_{0,1} \times L_{2,3} \times \ldots \times L_{2k+1 \times L_{C'}} \]

in $\mathcal{Y} = \mathcal{Y}_n \times \mathcal{Y}_m \times \ldots \times \mathcal{Y}_n$. If $\psi_i$ is the plurisubharmonic function on $\mathcal{Y}_i$ then $\mathcal{Y}$ is a Stein manifold with the plurisubharmonic function $\psi = \Sigma \psi_i$. 

Lemma 5.2.2. The Lagrangians $\mathcal{L}_i$, $i = 0, 1$ are allowable.

Proof. The Lagrangians are exact since they are simply connected submanifolds of exact manifolds. A point $m = (m_0, \ldots, m_{2k+1})$ of tangency of $\mathcal{L}_0$ to a level set of $\psi$ is a critical point of $\psi|_{\mathcal{L}_0}$. Since $\psi$ is the sum of the plurisubharmonic functions on each $\mathcal{Y}_i$, $m_i$ is a critical point of $\pi_i^* \psi|_{L_{i,i+1}}$. If $L_{i,i+1}$ is noncompact, it is a vanishing cycle on the diagonal either in $\mathcal{Y}_m \times \mathcal{Y}_{m+1}$ or in $\mathcal{Y}_{m+1} \times \mathcal{Y}_m$. In the first case $m_i$ is a critical point of $\pi_i^* \psi = \psi_i$ on $\mathcal{Y}_m$. Since $\mathcal{Y}_i$ and $\psi_i$ are algebraic, the critical point set is compact. The second case is similar. ∎

Theorem 5.2.3. For any tangle $T$, $HSS(T)$ is well-defined and is independent of the decomposition of $T$ into elementary tangles.

Proof. The finite intersection condition holds since the Lagrangian correspondences $L_{i,i+1}$ are proper (cf. 2.11.1). We take the parameter $R$ in the construction of the $L_\cap$ and $L_\cup$ so that all the intersection points are included in $M_{\leq R}$. Therefore by Proposition 2.11.3 the above Floer cohomology is well-defined. Note that since our Lagrangians are products of 2-spheres, they have a unique spin structure so the Floer cohomology groups above are modules over $\mathbb{Z}$. (cf. Theorem “Fs” in [7].) Independence of the decomposition follows from the Functoriality Theorem and theorem 5.1.8. ∎

It is clear that if $K$ is a $(0,0)$-tangle, i.e. a link, then the above invariant equals the original invariant of Seidel and Smith (4.6.1).
Chapter 6
The functor valued invariant

6.1 Fukaya categories and generalized Fukaya categories

According to [21] the generalized Fukaya category $\text{Fuk}^\#(M)$ of a symplectic manifold $M$ is an $A_\infty$ category whose objects are compact generalized Lagrangian correspondences between a point and $M$ and morphisms between two such objects $L_0$ and $L_1$ are the elements of Floer chain complex for $L_0^\# L_1$. The $A_\infty$ structure on $\text{Fuk}^\#(M)$ is given by counting holomorphic “quilted polygons”. More precisely the maps

$$\mu^d : CF(L_0, L_1) \otimes \cdots \otimes CF(L_{d-1}, L_d) \to CF(L_0, L_d) \quad (6.1)$$

are given by counting quilted $(d+1)$-gons whose boundary conditions are given by the $L_i$.

Here we need an enlargement of (generalized) Fukaya category of a Stein manifold to include noncompact admissible Lagrangians. For a Stein manifold $M$ we denote by $\text{Fuk}^\#(M)$ the $A_\infty$ category whose objects are allowable proper generalized Lagrangian correspondences between $M$ and a point. Symplectic manifolds involved in these correspondences can be either Stein or compact. Two such correspondences $L_0$ and $L_1$ satisfy the finite intersection property and we define the set of morphisms between them to be $CF(\mathcal{C}_c(L_0^\# L_1))$. Here we choose $c$ so as to include the intersection points of the Lagrangians. The $A_\infty$ structure is given in the same way as for the generalized Fukaya category of compact manifolds. Lemma 2.11.2 insures that the moduli spaces involved are compact.
6.2 \( A_\infty \) functor associated to a Lagrangian correspondence

Let \( L \) be a Lagrangian correspondence between two symplectic manifolds \( M \) and \( N \). Mau, Wehrheim and Woodward \([21]\) associate an \( A_\infty \) functor

\[
\Phi^\#_L : \text{Fuk}^\#(M) \to \text{Fuk}^\#(N).
\]  

At the level of objects it is given by

\[
\Phi^\#_L(L) = L^\# L.
\]

The higher maps

\[
\Phi^\#_{dL} : CF(L_0, L_1) \otimes \cdots \otimes CF(L_{d-1}, L_d) \to CF(\Phi^\#_L L_0, \Phi^\#_L L_d)
\]

are given by counting quilted discs.

6.3 The functor valued invariant

For an \((m, n)\) tangle \( T \), let \( \Phi(T) = (L_{0,1}, L_{1,2}, ..., L_{n-1,n}) \) be as in (5.2). We obtain an \( A_\infty \) functor

\[
\Phi^\#_T : \text{Fuk}^\#(\mathcal{Y}_m) \to \text{Fuk}^\#(\mathcal{Y}_n)
\]

which is given at the level of objects by \( \Phi^\#_T(L) = L^\# \Phi(T) \) for each \( L \in \text{Fuk}^\#(\mathcal{Y}_m) \). If \( K \) is a link then we obtain a functor

\[
\Phi^\#_K : \text{Fuk}^\#(pt) \to \text{Fuk}^\#(pt).
\]

Chapter 7

Results on the symplectic invariant

7.1 Some computations

In this section we compute $\mathcal{HSS}$ for elementary tangles. Set

$$\mathcal{V} = H^*(S^2)\{−1\}.$$ 

Remember that $\oplus$ denotes unlinked disjoint union. Let $\sigma_{i,m}^+$ and $\sigma_{i,m}^-$ be as in the Figure 3.4. If Lagrangians $L, L' \subset X \times \mathbb{C}^3$ are obtained from Lagrangians $K, K' \subset X$ by the relative vanishing cycle construction then we can isotope $L$ and $L'$ to $K \times S^2$ and $K' \times S^2$ inside a compact subset. Therefore we get

$$HF(L', L') = HF(K \times S^2, K' \times S^2) = HF(K, K') \otimes H^*(S^2)$$  \hfill (7.1)

For a tangle $T$ it follows from the above formula that

$$\mathcal{HSS}(T \oplus T') = \mathcal{HSS}(T) \otimes \mathcal{HSS}(T') \, (−1) = \mathcal{HSS}(T) \otimes \mathcal{V}.$$  \hfill (7.2)

The $−1$ degree shift here comes from the cup in $\bigodot$. More generally it follows from the commutation relations in section 5.1 that for any two tangles $kTl, mT'n$ we have

$$\Phi^\#(T \oplus T') = \Phi^\#(T \oplus id_m) \circ \Phi^\#(id_l \oplus T') = \Phi^\#(id_k \oplus T') \circ \Phi^\#(T \oplus id_n).$$  \hfill (7.3)

This gives an injection

$$\mathcal{HSS}(T \oplus T') \hookrightarrow \mathcal{HSS}(T) \otimes \mathcal{HSS}(T')$$  \hfill (7.4)

For links $L, L'$ this becomes an isomorphism

$$\mathcal{HSS}(L \oplus L') = \mathcal{HSS}(L) \otimes \mathcal{HSS}(L').$$  \hfill (7.5)
Following Khovanov [15] we define
\[ H^n = \mathcal{HSS}(id_n) = \bigoplus_{C,C' \in C_n} HF(L_{C'}, L_{C'}). \] (7.6)

It follows from (7.1) and 5.1.4 that each summand in the above direct sum equals \( H^*(S^2)^{\otimes k} \) where \( k \) is the number of circles made by attaching \( C' \) to \( C'' \). Therefore (7.6) equals Khovanov’s \( H^n \) as an abelian group.

**Lemma 7.1.1.** We have
\[
\mathcal{HSS} \ (\sigma_{i;m}^\pm) = \\
\left( (H^{m-1} \oplus \bar{H}^m \oplus H^m \oplus \bar{H}^m) \otimes \mathcal{V}\{1 \mp 2\} \right) \bigoplus H_2^m \otimes \mathcal{V}\{2\}.
\]
\[
\mathcal{HSS} \ (\cup_{i;m}) = (H^{m-1} \otimes \mathcal{V}) \bigoplus_{a \in C_m'} \oplus_{b \in C_{m-1}} HF(L_{a'}, L_b)
\]
\[
\mathcal{HSS} \ (\cap_{i;m}) = (H^{m-1} \otimes \mathcal{V}\{1\}) \bigoplus_{a \in C_m'} \oplus_{b \in C_{m-1}} HF(L_{a'}, L_b).
\]

**Proof.** The last two equalities are immediate consequences of (7.2). The computation for the first equality is similar to that of the rings \( H^m \). The only difference comes from the existence of braids \( \sigma_{i;m}^\pm \). As stated before if we modify the strands of \( a' \) passing through 1 and 2 in a small neighborhood of these two points then only the factors \( \mathcal{V}\{1\} \) and \( \mathcal{V}\{1\} \otimes \mathcal{V}\{1\} \) in (3.17) change. In the first four direct summands of the decomposition (3.17) the component of \( a'\sigma_{i;m}^\pm b \) containing the braid contributes the following.

\[ HF(L_{\cap_i} L_{\sigma_{i;m}^\pm}, L_{\cup_i})\{-w(\sigma_{i;m}^\pm)\} = HF(L_{\cap_i}\{\mp 1\}, L_{\cup_i})\{\mp 1\} = \mathcal{V}\{1 \mp 2\} \]

The second to last equality is because \( \sigma_{i;m}^+ = \sigma_{i;m} \) and \( \sigma_{i;m}^- = \sigma_{i;m}^{-1} \) when we ignore the orientation.

In the last direct summand in (3.17) the component of \( a'\sigma_{i;m}^\pm b \) containing the braid looks locally like the tangle \( T_0 \) depicted in Figure 7.1. (The figure depicts the case of \( \sigma_{i;m}^+ \) i.e. the crossing in the figure is \( \sigma_{i;m}^+ \)). It is equivalent to \( \cap_i \cap_{i+2} (\sigma_{i;m}^\pm) \cup_i \cup_{i+2} \). We can use the commutation relation (5.8) to get
\[ \cap_i \cap_{i+1} \sigma_{i,m}^{\pm}^{-1} \cup_i \cup_{i+2}. \] Therefore the contribution of \( T_0 \) is

\[
\begin{align*}
HF \ (L \cap_i L_{\cap_{i+1}} L_{\cap_{i+1}(\pm 1)}, L_{\cup_i} L_{\cup_{i+2}}) \{w(\sigma_{i,m}^{\pm})\} &= \\
HF \ (L \cap_i L_{\cap_{i+1}} L_{\cup_i} L_{\cup_{i+2}}) \{w(\sigma_{i,m}^{\pm})\} &= \\
HF \ (L \cap_i L_{\cup_i}) \{1\} &= \psi(2).
\end{align*}
\]

Where we have used commutation relations (5.7) and (5.11).

\[ \square \]

![Figure 7.1: Proof of Lemma 7.1.1](image)

### 7.2 Maps induced by cobordisms

In this section we study the maps induced by minimal cobordisms on \( \mathcal{HSS} \). Using elementary Morse theory one can decompose any cobordism between two tangles into three elementary types. We will assign a cobordism map \( \mathcal{HSS}(S) \) to each such elementary cobordism \( S \). Given a general cobordism \( S \) between two tangles \( T \) and \( T' \), we decompose it into elementary cobordisms

\[ S = S_l \circ S_{l-1} \circ \cdots \circ S_1 \]

and define \( \mathcal{HSS}(S) \) to be the composition \( \mathcal{HSS}(S_l) \circ \mathcal{HSS}(S_{l-1}) \circ \cdots \circ \mathcal{HSS}(S_1) \). Since such a decomposition is not unique, one can potentially get different maps from different decompositions. We will not address this problem here. Let \( T, T' \) be \((l, m)\) and \((m, n)\) tangles respectively.
**Type I.** Cobordisms, equivalent to trivial cobordism, between equivalent tangles. The (iso-)morphism assigned to such a cobordism is given by the Functoriality theorem. C.f. Theorem 5.2.3.

**Type II.** Birth or death of an unlinked circle:

\[ S_\bigcirc : T \circ T' \longrightarrow TT' \]  
\[ S'_\bigcirc : TT' \longrightarrow T \circ T'. \]  

Equation (7.2) gives us a canonical isomorphism

\[ \mathcal{HSS}(T \circ T') \cong \mathcal{HSS}(TT') \otimes_{\mathbb{Z}} \mathcal{V}. \]

We define the map

\[ \mathcal{HSS}(S_\bigcirc) : \mathcal{HSS}(T \circ T') \longrightarrow \mathcal{HSS}(TT') \]

induced by the cobordism \( S_\bigcirc \) to be \( id \otimes \varepsilon \) and the map

\[ \mathcal{HSS}(S'_\bigcirc) : \mathcal{HSS}(TT') \longrightarrow \mathcal{HSS}(T \circ T') \]

to be \( id \otimes \iota \). Here \( \varepsilon \) and \( \iota \) are the trace and unit maps from 3.2.

**Type III.** Saddle point cobordisms:

\[ S_{\cap_i} : T \cap_i \cup_i T' \longrightarrow TT' \]  
\[ S'_{\cap_i} : TT' \longrightarrow T \cap_i \cup_i T'. \]

Let \( \Phi(T), \Phi(T') \) be the generalized Lagrangian correspondences associated to them. We define the following cobordism maps as follows.

\[ \mathcal{CSS}(S_{\cap_i}) : \mathcal{CSS}(T \cup_i \cap_i T') \longrightarrow \mathcal{CSS}(TT') \]  
\[ \mathcal{CSS}(S'_{\cap_i}) : \mathcal{CSS}(TT') \longrightarrow \mathcal{CSS}(T \cup_i \cap_i T') \]

The homomorphism (7.13) is defined to be the relative invariant associated to the quilt in Figure 7.2. The homomorphism (7.14) is the relative invariant of
the transpose of this quilt. We can use the local picture of the Lemma 4.1.5 to obtain a local isomorphism $\mathcal{Y}_{m_j} \cong \mathcal{Y}_{m_j-1} \times \mathcal{Y}_1$ and the Lemma 4.3.1 to get $L_{\cap_i} \cong \mathcal{Y}_{m-1} \times S^2$. Thus $\mathcal{CSS}(S_{\cap_i})$ becomes the tensor product of the relative maps of the quilts in Figure 7.2. Therefore the degrees of the relative maps of the quilt $Q_0$ and $Q'_0$ can be taken to be zero. See also Lemma 7.6.2 below. (In fact we do not need this local picture to show that the degree of $CF(Q'_0)$ is zero.) However because of the $-1$ degree shift coming from the extra cap in $T \cup_i \cap_i T'$ we get

$$\deg \mathcal{CSS}(S_{\cap_1}) = 1 = \deg \mathcal{CSS}(S_{\cap_1}').$$

(7.15)

**Minimal cobordisms** (C.f. Definition 3.3.2) are a special combination of saddle cobordisms which deserve special attention. Let $a \in \mathcal{C}_i, b \in \mathcal{C}_m$ and $c \in \mathcal{C}_n$. Recall from section 3.3 that we denote the minimal cobordism $b'b \rightarrow id$ by $S_b$. From $S_b$ we get the cobordism $1_a1_T S_b1_T 1_c$ between $aTbb'T'c$ and $aTT'c$. We associated to this cobordism the quilt depicted in Figure 7.2 and we denote it by $Q_b$. The relative invariant associated to $Q_b$ gives a homomorphism of chain complexes
Figure 7.3: Decomposing the quilt associated to a saddle cobordism

Figure 7.4: Quilt associated to a minimal cobordism
\[
\text{CF}(Q_b) : \quad \text{CF}(L_a^t, \Phi(T), L_b) \otimes \mathbb{Z} \text{CF}(L_b^t, \Phi(T'), L_c) \longrightarrow \text{CF}(L_a^t, \Phi(T \circ T'), L_c). 
\]

(7.16)

as well as a homomorphism of graded groups

\[
\mathcal{HSS}(S_b) := \text{HF}(Q_b) : \text{HF}(L_a^t, \Phi(T), L_b) \otimes \text{HF}(L_b^t, \Phi(T'), L_c) \rightarrow \text{HF}(L_a^t, \Phi(T \circ T'), L_c).
\]

(7.17)

Summing over all such \(a, b\) and \(c\) we get maps

\[
\mathcal{CSS}(S_b) : \quad \mathcal{CSS}(T) \otimes \mathbb{Z} \mathcal{CSS}(T') \longrightarrow \mathcal{CSS}(TT')
\]

(7.18)

and

\[
\mathcal{HSS}(S_b) : \quad \mathcal{HSS}(T) \otimes \mathcal{HSS}(T') \longrightarrow \mathcal{HSS}(TT').
\]

(7.19)

If \(Q_b^t\) is obtained from \(Q_b\) by reversing the incoming and outgoing ends we get

\[
\mathcal{HSS}(S_b^t) : \mathcal{HSS}(T \circ T') \rightarrow \mathcal{HSS}(\Phi(T)) \otimes \mathbb{Z} \mathcal{HSS}(T').
\]

(7.20)

It follows from the formula for the degree of the relative map of a quilt (Formula (33) in [39]) that

\[
\deg \mathcal{CSS}(S_b) = 0 = \deg \mathcal{CSS}(S_b^t).
\]

(7.21)

In the case that \(T = T' = id_1\) we get maps

\[
m_{\text{sympl}} : H^{*+1}(S^2) \otimes H^*(S^2) \rightarrow H^{*+1}(S^2)
\]

(7.22)

and

\[
\Delta_{\text{sympl}} : H^{*+1}(S^2) \rightarrow H^{*+1}(S^2) \otimes H^*(S^2).
\]

(7.23)

**Lemma 7.2.1.** We have \(m_{\text{sympl}} = m\) and \(\Delta_{\text{sympl}} = \Delta\).
Proof. Let \( f_0, f_1, f_2 \) be three Morse functions on a Riemannian manifold \( M \). Fukaya and Oh [6] (See also [10]) prove that if we equip the cotangent bundle of \( M \) with the almost complex structure induced by the Levi-Civita connection on \( M \) then, for generic choice of the \( f_i \), there is an orientation preserving diffeomorphism between the moduli space of pseudoholomorphic triangles connecting intersection points of the \( df_i \) and the moduli space of pair of pants trajectories between the corresponding critical points of \( f_0 - f_1, f_1 - f_2, f_2 - f_0 \). The moduli space of triangles in \( T^* S^2 \) with the almost complex structure from \( \mathcal{Y}_1 \) is zero dimensional and cobordant to the moduli corresponding to the structure induced by Levi-Civita connection. So the signed sum of the elements of the two are equal. Therefore (7.22) equals the wedge product on \( H^*(S^2) \) so \( m_{\text{symp}} = m \). The same arguments show that \( \Delta_{\text{symp}} \) corresponds to the operation given by counting inverted Y’s in Morse homology so upon choosing generators \( 1, X \) for \( H^*(S^1) \) we get \( \Delta_{\text{symp}}(1) = 1 \otimes X + X \otimes 1 \) and \( \Delta_{\text{symp}}(X) = X \otimes X \). Therefor \( \Delta_{\text{symp}} = \Delta \). In fact the above maps \( m_{\text{symp}} \) and \( \Delta_{\text{symp}} \) give a basis-free definition of the homomorphisms \( m, \Delta \).

In order to understand the behavior of the maps (7.17) and (7.20) in general we need the following lemma which is a relative versions of “Kunneth formula for Floer homology” in [35].

Lemma 7.2.2. Assume \( Y = X \times \mathbb{C}^3 \) is a Kähler manifold and \( X \) is given the induced metric. Let \( K, K', K'' \) be Lagrangian submanifolds of \( X \) and \( L, L'', L''' \) be obtained from them by relative vanishing cycle construction. Then we have the following commutative diagram

\[
\begin{array}{ccc}
HF(L, L') \otimes H^*(S^2) & \longrightarrow & HF(L, L'') \\
\downarrow & & \downarrow \\
HF(K, K') \otimes H^*(S^2) & \longrightarrow & HF(K, K'') \otimes H^*(S^2)
\end{array}
\]

\[
\begin{array}{ccc}
HF(L', L'') & \longrightarrow & HF(L', L''') \\
\downarrow & & \downarrow \\
HF(K, K') \otimes H^*(S^2) & \longrightarrow & HF(K, K''') \otimes H^*(S^2)
\end{array}
\]
where the lower horizontal maps factor through tensor products.

Proof. We first obtain a localization result for the holomorphic triangles $u$ with boundary on $L, L', L''$. Then we isotope these Lagrangians to $K \times S^2, K' \times S^2, K'' \times S^2$ within that neighborhood. Now we have $u = (u_0, u_1)$ where $u_0$ is a triangle in $X$ with boundary condition $K, K', K''$ and $u_1$ is a triangle in $C^2$ with boundary on $S^2, S^2, S^2$. The lemma follows.

Note that the horizontal composition $SS'$ of two cobordisms $S$ and $S'$ equals $(S \text{id}) \circ (\text{id} S')$.

Lemma 7.2.3. For two minimal cobordisms $S_a$ and $S_b$ we have

$$
\mathcal{HSS}(S_a \text{id}) \circ \mathcal{HSS}(\text{id} S_b) = \mathcal{HSS}(\text{id} S_b) \circ \mathcal{HSS}(S_a \text{id}).
$$

(7.24)

Proof. From [39] we know if $Q$ and $Q'$ are two quilts which can be composed vertically (i.e. along the strip-like ends) then $HF(Q \circ Q') = HF(Q) \circ HF(Q')$. We also know that $HF(Q)$ is (at the cohomology level) invariant under the isotopy of the quilt $Q$. The lemma follows from these two facts together with the isotopy in Figure 7.2.

![Figure 7.5: Isotopy between the composition of two quilts](image)

Lemma 7.2.4. Let $T_0, T_1, T'_0, T'_1$ be tangles such that $T_i \simeq T'_i$ for $i = 0, 1$ then we have the following commutative diagram

$$
\begin{array}{ccc}
HF(a', \Phi(T_0), b) & \otimes & HF(b', \Phi(T_1), c) \\
\downarrow & & \downarrow \\
HF(a', \Phi(T'_0), b) & \otimes & HF(b', \Phi(T'_1), c)
\end{array}
$$

where the vertical maps are isomorphisms.
Proof. The vertical isomorphisms were constructed by showing that Lagrangian correspondences assigned to elementary tangles satisfy the same commutation relations as the corresponding tangles. So they are given by Hamiltonian isotoping the corresponding Lagrangians and the Functoriality theorem. For the first kind, the Hamiltonian isotopy induces a diffeomorphism between the corresponding moduli spaces of quilts. The second kind is an instance of “shrinking strips in quilted surfaces ” and commutativity is given, in general settings, by Theorem 5.4.1 in [39].

7.3 \( H^n \) module structure

We define the symplectic analogue of the rings \( H^n \) as

\[
H^n_{\text{sym}} = \mathcal{HSS}(id_n) = \bigoplus_{a,b \in C_n} HF(L_a^t, L_b).
\]

The product map from \( HF(L_a^t, L_b) \otimes HF(L_c^t, L_d) \) to \( HF(L_a^t, L_d) \) is given by zero if \( b \neq d \) and is given by the map \( HF(Q_b) \) otherwise.

Lemma 7.3.1. For any \( a, b \in C_m \) we have \( HF(L_a^t, L_b) \cong H^*(S^2)^{\otimes k} \cong \mathcal{P}^{\otimes k}\{k\} \) where \( k \) is the number of circles in \( a^t b \).

Proof. The Lagrangian \( L_a \) equals the composition of the Lagrangians associated to its arcs and similarly for \( L_b \) so \( \Phi(a^t)\# \Phi(b) = \Phi(a^t b) \). Therefore

\[
HF(L_{a}^t, L_{b}) = HF(\Phi(a^t), \Phi(b))\{m\} = HF(\Phi(a^t b))\{m\} = \mathcal{HSS}(\Phi(k\bigcirc))\{m\} = H^*(S^2)^{\otimes k}.
\]

Proposition 7.3.2. For any \( n \) we have

\[
H^n_{\text{sym}} \cong H^n
\]

as graded rings.
**Proof.** The above lemma gives the isomorphism as graded abelian groups. Since for any \( a, b \in C_m \), \( a \sim b \) is equivalent to a number of unlinked circles, lemmas 7.2.4 and 7.2.2 give isomorphism of ring structures.

Therefore we drop the subscript \( \text{symp} \) in \( H^n_{\text{symp}} \) from now on. For an \((l, m)\)-tangle \( T \), \( \mathcal{HSS}(T) \) has a structure of a \((H^l, H^m)\) bimodule as follows. We have

\[
\mathcal{HSS}(T) = \bigoplus_{b \in C_l, c \in C_m} HF(L_b, \Phi(T), L_c).
\]

The ring \( aH^l_b \) acts on \( HF(b, \Phi(T), c) \) from left by the map \( \mathcal{HSS}(S_b) \) (in (7.19)). So does \( cH^m_d \) from right by the map \( \mathcal{HSS}(S_c) \). We set the left action of \( aH^l_b \) on \( HF(b, \Phi(T), c) \) to be zero if \( b \neq b' \) and similarly for the right action. This way we obtain an \((H^l, H^m)\)-bimodule structure on \( \mathcal{HSS}(T) \).

**Remark 7.3.3.** Note that since the cobordism maps \( \mathcal{CSS}(S_b) \) are of degree zero, the chain complex \( \mathcal{CSS}(T) \) can be regarded as a chain complex of \((H^l, H^m)\)-bimodules.

**Lemma 7.3.4.** With the same notation as in (3.17) we have

\[
\begin{align*}
\mathcal{HSS}(id_m) &= H^m = \mathcal{K}\Phi(id_m) \\
\mathcal{HSS}(\cap_{i;m}) &= \mathcal{K}\Phi(\cap_{i;m}) \\
\mathcal{HSS}(\cup_{i;m}) &= \mathcal{K}\Phi(\cup_{i;m}) \\
\mathcal{HSS}(\sigma^\pm_{i;m}) &= \overline{\mathcal{K}\Phi(\sigma^\pm_{i;m})} = (H^{m-1} \oplus H^{m'} \oplus H^{m'} \oplus H^m_1) \otimes \mathcal{V}\{1 \mp 2\} \bigoplus H^m_2 \otimes \mathcal{V}\{2\}
\end{align*}
\]

as \( H^m \) modules.

**Proof.** The first three equations follow from the fact that \( \mathcal{K}\Phi \) and \( \mathcal{HSS} \) for disjoint union of \( k \) circles are equal to \( \mathcal{V} \otimes k \). For the last one, the first equality was proved in 7.1.1 and the second one in the lemma 3.5.2. 

\( \square \)
7.4 Functoriality of the invariant for flat tangles

Let $T$ and $T'$ be $(l, m)$ and $(m, n)$ tangles respectively. Consider the map $\psi_s$

\[
\begin{array}{c}
\mathcal{HSS}(T) \otimes_{\mathbb{Z}} \mathcal{HSS}(T') \\
\bigoplus_{a,b,b',c} HF(L_a^l, \Phi(T), L_b) \otimes_{\mathbb{Z}} HF(L_b^m, \Phi(T'), L_c) \\
\bigoplus_{a,c} HF(L_a^l, \Phi(T' \circ T), L_c)
\end{array}
\]

which is zero if $b \neq b'$ and equals $\mathcal{HSS}(1_a 1_T S_b 1_{T'} 1_c)$ otherwise. Here, as before, $S_b$ is the minimal cobordism between $bb'$ and $id_m$. The abelian group $\mathcal{HSS}(T) \otimes_{\mathbb{Z}} \mathcal{HSS}(T')$ has the structure of a $(H^l, H^n)$-bimodule and $\psi$ is a $(H^l, H^n)$-bimodule map. If $x \in HF(L_a^l, \Phi(T), L_b)$, $y \in HF(L_b^m, \Phi(T'), L_c)$ and $\xi \in b\mathcal{H}^m_{b'}$

then

\[
\begin{align*}
\psi_s(x \xi \otimes y) &= \mathcal{HSS}(1_a 1_T S_{b'} 1_{T'} 1_c) \mathcal{HSS}(1_a 1_T S_b 1_{b'} 1_{T'} 1_c)(x, y) \\
\psi_s(x \otimes \xi y) &= \mathcal{HSS}(1_a 1_T S_{b} 1_{T'} 1_c) \mathcal{HSS}(1_a 1_T 1_b S_{b'} 1_{T'} 1_c)(x, y)
\end{align*}
\]

It follows from (7.24) that these two are equal and so $\psi_s$ factors through a map of bimodules $\mathcal{HSS}(T) \otimes_{H^m} \mathcal{HSS}(T') \to \mathcal{HSS}(T \circ T')$ which we still denote by $\psi_s$.

Lemma 7.4.1. If $T$ and $T'$ are flat then $\psi_s$ gives an isomorphism

\[
\psi_s : \mathcal{HSS}(T) \otimes_{H^m} \mathcal{HSS}(T') \cong \mathcal{HSS}(T \circ T').
\]

Proof. Proof is exactly the same as that of Theorem 1 in [15]. The map $\psi$ is the direct sum of the maps

\[
a \psi_c : \bigoplus_{b} HF(L_a^l, \Phi(T), L_b) \bigotimes_{H^m} \bigoplus_{b'} HF(L_b^{m'}, \Phi(T'), L_c) \to HF(L_a^l, \Phi(T \circ T'), L_c)
\]

We have $\bigoplus_{b} HF(L_a^l, \Phi(T), L_b) \cong \mathcal{HSS}(a'T)$ and

\[
\bigoplus_{b'} HF(L_b^{m'}, \Phi(T'), L_c) \cong \mathcal{HSS}(T') \{n\}
\]
as left and right $H^m$-modules respectively. We also have $HF(L^t_a, \Phi(T \circ T'), L_c) \cong \mathcal{HSS}(aTT' c)\{n\}$. Therefore the argument is reduced to showing that

$$\mathcal{HSS}(a^t T) \otimes_{H^m} \mathcal{HSS}(T' c) \cong \mathcal{HSS}(a'T T' c).$$

Now $a^t T$ and $T' c$ are $(0, m)$ and $(m, 0)$-tangles respectively so $a^t T = a' \oplus i \bigcirc$ and $T' c = c' \oplus j \bigcirc$ where $a', b' \in C_m$ and $i$ and $j$ are the number of circles in $a^t T$ and $T' c$ respectively. Thus we have $\mathcal{HSS}(a^t T) = \mathcal{HSS}(a') \otimes \mathcal{V}^i$, $\mathcal{HSS}(T' c) = \mathcal{HSS}(c') \otimes \mathcal{V}^j$ and $\mathcal{HSS}(a'T T' c) = \mathcal{HSS}(a' c') \otimes \mathcal{V}^{i+j}$. So we need to show that

$$\mathcal{HSS}(a') \otimes_{H^m} \mathcal{HSS}(c') = \mathcal{HSS}(a' c').$$

We have $H^m \otimes_{H^m} H^m = H^m$ and if we multiply this identity with the idempotent $1_{a'}$ from left and by $1_{c'}$ from right we get the desired result. \[]

We will need a slight generalization of this result.

**Definition 7.4.2.** A tangle $T$ is called semiflat if for all crossingless matchings $a, b$, the tangle $a^t T b$ is flat.

**Lemma 7.4.3.** If $T, T'$ and $T \circ T'$ are semiflat then $\psi_s$ is an isomorphism.

**Proof.** Note that for any crossingless matching $a, b$, $\mathcal{HSS}(aT b)$ has the structure of a right $b H^m_b$ module and this module structure agrees with the one induced from $H^m$ module structure on $\mathcal{HSS}(T)$. The same is true for $\mathcal{HSS}(b T' c)$ as a left $c H^m_c$ module. We will show that

$$\psi_s : \mathcal{HSS}(aT b) \otimes b H^m_b \mathcal{HSS}(b T' c) \rightarrow \mathcal{HSS}(a T \circ T' c)$$

is an isomorphism for any $a, b$ and $c$. Since the multiplication map

$$HF(L^t_a, \Phi(T), L_b) \otimes_{Z} HF(L^n_b, \Phi(T'), L_c) \xrightarrow{\psi_s} HF(L^t_a, \Phi(T' \circ T), L_c)$$

is zero if $b \neq b'$ this proves the lemma. It follows from the assumption that $\Phi(aT b), \Phi(b T' c)$ and $\Phi(a T \circ T' c)$ are isomorphic to $\Phi(i)$, $\Phi(j)$ and $\Phi(k)$ respectively in the symplectic category for some $i$ and $j$. By “shrinking strips
in a quilt” (Theorem 5.4.1 in [39]), we have the following commutative diagram where the lower map is induced by the same cobordism as the top map.

\[
\begin{array}{c}
\mathcal{HSS}(aTb) \otimes_{b} H_{b}^{m} \mathcal{HSS}(bT'c) \rightarrow \mathcal{HSS}(aTT'c) \\
\downarrow \\
\mathcal{HSS}(\bigcirc^{i}) \otimes_{b} H_{b}^{m} \mathcal{HSS}(\bigcirc^{j}) \rightarrow \mathcal{HSS}(\bigcirc^{k})
\end{array}
\]

The lower homomorphisms is a composition of maps induced by cobordisms in which either two circles join at some \(n\) points or one circle decomposes to \(n\) circles. In each case each point of join or decomposition corresponds to an element of \(b\). The first kind of map induces a homomorphism

\[
\mathcal{V}' \otimes_{\mathcal{V} \otimes \mathcal{V}} \mathcal{V} \rightarrow \mathcal{V}
\]

given by the product \(m\) and the second type induces a map

\[
\mathcal{V}' \rightarrow \mathcal{V} \otimes_{\mathcal{V}' \otimes \mathcal{V}} \mathcal{V} \otimes_{\mathcal{V} \otimes \mathcal{V}} \cdots \otimes_{\mathcal{V}} \mathcal{V}
\]

given by the coproduct \(\Delta\). Each map is clearly an isomorphism.

\[\square\]

**Corollary 7.4.4.** For any flat tangle \(T\) we have

\[
\mathcal{HSS}(T) = \overline{\mathcal{Kh}}(T) = \mathcal{Kh}(T).
\]

**Proof.** This follows from (3.30), 7.4.1 and 7.3.4. \[\square\]

**Lemma 7.4.5.** Let \(T, T'\) be flat \((m, n)\)-tangles and \(S\) a cobordism between \(T\) and \(T'\) which equals a composition of minimal cobordisms. Then we have

\[
\mathcal{HSS}(S) = \mathcal{Kh}(S).
\] (7.26)

**Proof.** By (7.24) we can assume that \(S\) consists of a single minimal cobordism. Therefore we have \(T = T_{1}ccT_{2}\) and \(T' = T_{1}idT_{2}\) for a crossingless matching \(c\) and \(S\) equals \(1_{T_{1}}Sc1_{T_{2}}\). For any \(a \in C_{m}\) and \(b \in C_{n}\), \(aT_{1}\) equals a crossingless matching \(a'_{1} \in C_{m}\) disjoint union with some \(k\) circles. The same is true for \(T_{2}b\)
i.e. \( T_2 b \) equals \( b_2 \in C_n \), disjoint union with \( l \) circles. So, the problem is reduced to showing that the map

\[
\mathcal{HS}(S) = HF(Q_c) : HF(L^t_{a_1}, L^t_c, L^t_{b_2}) \otimes \mathbb{Q}^{k+l} \to HF(L^t_{a_1}, L^t_{b_2}) \otimes \mathbb{Q}^{k+l}
\]
equals \( \mathcal{H}_{S}(S) \). But

\[
HF(L^t_{a_1}, L^t_c, L^t_{b_2}) = HF(L^t_{a_1}, L_c) \otimes HF(L^t_c, L_{b_2}) = a_1 H_c \otimes c H_{b_2}
\]
and \( HF(L^t_{a_1}, L_{b_2}) = a_1 H_{b_2} \). Therefore the lemma follows from the equality of the ring structures on \( H^m \) and \( H^m_{\text{symp}} \) (Lemma 7.3.2).

\[ \Box \]

7.5 Vanishing of the differential for flat tangles

**Lemma 7.5.1.** Let \( C_1, C_2 \in C_m \) be two crossingless matchings. Then we can choose Floer data in such a way that the Floer chain complex \( CF(L_{C_1}, L_{C_2}) \) has differential equal to zero.

**Proof.** We prove by induction on \( m \). If \( m = 1 \) then there is only one crossingless matching and the Floer chain complex equals \( CF(S^2, S^2) \) where \( S^2 \) is the zero section in \( \mathcal{Y}_m = T^* S^2 \). We can Hamiltonian isotope the zero section to a Lagrangian \( L \) s.t. \( L \) intersects the zero section at only two points. For example we can take \( L \) to be the graph of the one-form \( df \) where \( f \) is the height function on the zero section. In this case the Floer differential has to be zero because otherwise \( HF(S^2, L) \) will not be equal to \( H^*(S^2) \). This can also be seen by considering the Maslov indices of intersection points.

Now assume the statement holds for all crossingless matchings in \( C_k \) for \( k < m \). Let \( \alpha_1 \) be an arbitrary arc in \( C_1 \) and \( \mu_1, \mu_2 \) its endpoints. There are two cases. Either there is an arc \( \alpha_2 \) in \( C_2 \) joining \( p \) and \( q \) or there is no such arc. Proof for these two cases are similar to the proofs of the Kunneth formula and the Thom isomorphism for Floer homology \([35]\). In the first case let \( \tilde{C}_i \) be obtained from \( C_i \) by deleting \( \alpha_i, i = 1, 2 \). Then we can use lemma 4.1.3 and then isotope
the induced metric into the product metric. So $L_{C_i}$ gets isotoped to $L_{\bar{C_i}} \times S^2$

We choose a time dependent almost complex structure $\bar{J}_t$ on the base which is a compactly supported perturbation of its standard structure $J_0$. We choose the almost complex structure on the total space to be equal to the product $\bar{J}_t \oplus J_{C^3}$ in a small neighborhood $U_0$ of the zero section and equal to $J_0 \oplus J_{C^3}$ outside an open set $U_1$ containing $\bar{U}_0$. This way we can obtain an almost complex structure which is both regular and has similar properties to the product structure inside $U_0$. Since our pseudoholomorphic strips are confined to $U_0$, we have

$$CF(L_{C_1}, L_{C_2}) = CF(L_{\bar{C_1}}, L_{\bar{C_2}}) \otimes CF(S^2, S^2).$$

So the claim follows from the induction hypothesis and the argument for the base case. In the second case let $\alpha_2$ be the unique arc in $C_2$ which has $\mu_2$ as an endpoint and let $\mu_3$ be its other end point. Now we can use lemma 4.1.5 to identify $L_{C_i}$ with $L_{\bar{C_i}} \times S^1 \Lambda_\alpha_i$, where $\Lambda_\alpha$ is the lagrangian sphere associated to the curve $\alpha$ as defined in section 4.3. We choose the almost complex structure in a way similar to that of the first case above. Note that there are two possible configurations of the curves $\alpha_i$.

In either case $\Lambda_{\alpha_1}$ and $\Lambda_{\alpha_2}$ intersect at only one point $p$ corresponding to $\mu_2$. So we have

$$CF(L_{C_1}, L_{C_2}) = CF(L_{\bar{C_1}}, L_{\bar{C_2}}) \otimes \mathbb{Z} < p > .$$

Let $u$ be a holomorphic strip joining to intersection points of $L_{C_1}$ and $L_{C_2}$. So we have $u = (u', u'')$ where $u'$ is the projection to the first factor. By the induction hypothesis, $u'$ is constant. Projection to the second factor is a holomorphic strip in $\mathbb{C}$ which has its boundary on $\alpha_1$ and $\alpha_2$. Such a finite energy curve has to be constant by the exponential convergence property of pseudoholomorphic strips. Therefore $u''$ is also constant so we get the desired result.

\[\square\]

**Lemma 7.5.2.** Let $T$ be a flat $(m,n)$-tangle. We can choose the Floer data in such a way that the Floer chain complex whose cohomology is $\mathcal{HSS}(T)$ has
differential equal to zero.

Proof. Let \(T = T_1 \cdots T_{k-1}\) be a decomposition of \(T\) and let \(T_0 \in \mathcal{C}_m\) and \(T_k \in \mathcal{C}_n\). Let \(L_{T_i}\) be a correspondence between \(\mathcal{Y}_{m_i}\) and \(\mathcal{Y}_{m_{i+1}}\). We use induction on \(m = \sum m_i\). The case \(m = 1\) was treated in Lemma 7.5.1. If \(T_1\) is the identity tangle then \(CF(L_{T_0}, L_{T_1}, \cdots, L_{T_k}) = CF(L_{T_0}, L_{T_2}, \cdots, L_{T_k})\). So we can assume that \(T_1\) is a cup. Therefore the both \(L_{T_0}\) and \(L_{T_1}\) are obtained by relative vanishing cycle construction from Lagrangians in \(\mathcal{Y}_{m_0-1}\) and \(\mathcal{Y}_{m_0-1} \times \mathcal{Y}_{m_1}\). Therefore we can use the same argument as in the proof of 7.5.1 for the induction step.

Definition 7.5.3. For a flat \((m, n)\)-tangle \(T\) we require the chain complex

\[
\mathcal{CSS}(T) = \bigoplus_{a \in \mathcal{C}_m, b \in \mathcal{C}_n} CF(L_a^T, \Phi(T), L_b)
\]

to be given by Floer data in lemma 7.5.2.

From 7.5.2 and 7.4.1 we get the following.

Corollary 7.5.4. Let \(T\) and \(T'\) be \((l, m)\) and \((m, n)\) flat tangles respectively. We have

\[
\mathcal{CSS}(T \circ T') = \mathcal{CSS}(T) \otimes_{H^\mathbb{Z}} \mathcal{CSS}(T').
\]

7.6 Exact triangle for the symplectic invariant

In this section we prove an exact triangle for the Seidel-Smith invariant which is analogous to skein relations for knot polynomials. The tool we use is the exact triangle for Lagrangian Floer homology. This exact triangle was discovered by Seidel [33] for Dehn twists. We use a generalization of this triangle to fibred Dehn twists due to Wehrheim and Woodward [37]. Let \(M\) be a symplectic manifold and \(C \subset M\) a spherically fibred coisotropic fibering over a base \(B\). We denote the fibred Dehn twist around \(C\) by \(\tau_C\). The embedding \((\iota \times \pi)C\) is a Lagrangian submanifold of \(M^- \times B\). By the abuse of notation we sometimes denote this submanifold by \(C\).
Let $Q_0$ be the quilt in the Figure 7.6. The exact triangle in [37] establishes a quasi-isomorphism between the Floer chain complex $CF(L, \tau_C L')$ and the cone of the morphism $f := CF(Q_0)$, i.e. the relative map associated with $Q_0$.

\[ f = CF(Q_0) : \quad CF(L, (\pi \times \iota)C^t, (\iota \times \pi)C, L')\{-\frac{1}{2} \dim B\} \longrightarrow CF(L, L'). \]

(7.27)

![Figure 7.6: The quilt used in the exact triangle](image)

More precisely we have the following.

**Theorem 7.6.1** (Wehrheim, Woodward [37]). If $C$ has codimension at least two and the triple $(L_0, L_1, C)$ is monotone and has Maslov index greater than or equal 3 then there is a quasi-isomorphism $(h\{1\}, k)$ from

\[ \text{Cone}(f) = CF(L, C^t, C, L')\{-\frac{1}{2} \dim B + 1\} \bigoplus CF(L, L') \]

to $CF(L, \tau_C L')$.

At the $A_\infty$ level one has the following exact triangle in $\text{DFuk}^\#(M)$. 
If $L = (L_k, L_{k-1}, \ldots, L_1)$ is any generalized Lagrangian submanifold of $M$ then by applying the $A_\infty$ functor $\Phi^\#_L = \Phi^\#_{L_k} \circ \cdots \circ \Phi^\#_{L_1}$ to (7.6) we get the following exact triangle in $\text{DFuk}^\#(M)$.

Therefore theorem 7.6.1 holds, without any change, if $L, L'$ are generalized Lagrangian submanifolds of $M$. One can prove this fact without using Fukaya categories. We use the following.

With the same assumptions as in 7.6.1 let $M = M_1 \times M_2$, $B = B_1 \times M_2$, and $C$ be of the form $C_1 \times M_2$ where $C_1$ is a sphere bundle over $B_1$. Further assume that there are Lagrangian submanifolds $L_i \subset M_i$ and $L'_i \subset M'_i$ for $i = 1, 2$ such that $L = L_1 \times L_2$ and $L' = L'_1 \times L'_2$. Let $d = -\frac{1}{2} \dim B$ and $d_1 = -\frac{1}{2} \dim B_1$.

Consider the map

$$CF(\bar{Q}_0): CF(L_1, C^t_1, C_1, L'_1)^{\{\frac{1}{2} \dim B_1\}} \longrightarrow CF(L_1, L'_1). \quad (7.28)$$

**Corollary 7.6.2.** Then $CF(L, \tau_C L')$ is quasi-isomorphic to

$$\text{Cone}(\bar{Q}) \otimes CF(L_2, L'_2) \quad (7.29)$$

and we have a commutative diagram

$$
\begin{array}{ccc}
CF(L, C^t, C, L')^d & \overset{CF(\bar{Q}_0)}{\longrightarrow} & CF(L, L') \\
\downarrow^{\{\frac{1}{2} \dim M_2\}} & & \downarrow \\
CF(L_1, C^t_1, C_1, L'_1)^{d_1} \otimes CF(L_2, L'_2)^{CF(\bar{Q}_0)} & \longrightarrow & CF(L_1, L'_1) \otimes CF(L_2, L'_2)
\end{array}
$$
Proof. We observe that $\tau_C = \tau_C \times id_{M_2}$. The homomorphism $CF(Q)$ is isomorphic to the tensor product of the maps induced by the two quilts in the Figure 7.7. The quilt on the left is $Q$ and the quilt on the right induces the identity map. There is a grading shift $CF(L_2, \Delta_{M_2}, \Delta_{M_2}, L'_2) = CF(L_2, L'_2)\{\frac{1}{2} \dim M_2\}$ coming from (2.16). \hfill \Box

**Proposition 7.6.3.** With the same assumptions as in Theorem 7.6.1, let $L, L'$ be two generalized Lagrangian submanifolds of $M$. Then $CF(L^t, \text{graph}(\tau_C), L')$ is quasi-isomorphic to the cone of the map

$$CF(L^t, C^t, C, L')\{1/2 \dim B\} \longrightarrow CF(L^t, L')$$

(7.30)

Proof. Let $L = (L_n, \cdots, L_k)$ and $L' = (L_{k-1}, \cdots, L_1)$ where $L_i \subset M_{i+1} \times M_i$ and $M_k = M$. We can assume, by adding identity Lagrangian correspondences if necessary, that

$$L_0 = L_n \times L_{n-2} \times \cdots \times L_k \times L_{k-1} \times \cdots \times L_2$$

and

$$L_1 = L_{n-1} \times L_{n-3} \times \cdots \times \text{graph}(\tau_C) \times \cdots \times L_1.$$  

We have $L_1 = \tau_C(L_{n-1} \times L_{n-3} \times \cdots \times L_1)$ where $C^t = M_{n+1} \times \cdots \times M_{k+1} \times C \times M_{k-1} \times \cdots \times M_1$ which fibers over $M_{n-1} \times \cdots \times B \times \cdots \times M_1$. The result follows from 7.6.2 by taking $M_1 = M = M_k$ and $M_2$ to be the product of the rest of the manifolds $M_i$. \hfill \Box

**Corollary 7.6.4.** $CF(L, \tau_C^{-1}L')$ is quasi-isomorphic to the cone $\text{Cone} (CF(Q^t_{\text{t}0})) \{1\}$.

Proof. This is a standard argument. If $l = \dim L$ then we have

$$CF^*(L, \tau_C^{-1}L') = CF^*(\tau_C L, L') = CF^{l-*}(L', \tau_C L)^\vee = \text{Hom}(CF^{l-*}(L', \tau_C L), \mathbb{Z}).$$

It follows from 7.6.1 that this is quasi-isomorphic to

$$CF^{l-*}(L', (\iota \times \pi)C, (\pi \times \iota)C^t, L)\{1\}^\vee \oplus CF^{l-*}(L', L)^\vee$$
Figure 7.7: Decomposition of the cone in Corollary 7.6.2

(with appropriate differential). This in turn equals

$$CF(L, L') \bigoplus CF(L, (\iota \times \pi)C^t, (\pi \times \iota)C^t, L')\{-1\}.$$ 

Now we use Theorem 7.6.1 (or more precisely 7.6.3) to obtain an exact triangle for the Seidel-Smith invariant. In the case under study $M = \mathcal{Y}_l$ and the spherically fibred isotropic is $C = L_{\epsilon_l}$. The coisotropic submanifold $C$ is a sphere bundle over $B = \mathcal{Y}_{l-1}$. By Theorem 5.1.1, the fibred Dehn twist $\tau_C$ along $C$ equals the monodromy map $h_{\sigma_i}$ and so for any Lagrangian $L \subset M$ we have

$$L_{\sigma_i} \circ L \simeq \tau_C L.$$  \hspace{1cm}(7.31)

Therefore using the local picture of the Lemma 4.1.3 we see that if we have a subset $B \subset \mathcal{Y}_m$ for which the naive (non-rescaled) parallel transport map $h_{\sigma_i}|_B$ is well-defined then

$$h_{\sigma_i} \simeq \tau_{\mathcal{Y}_i}.$$  \hspace{1cm}(7.32)

The reason is that since the naive parallel transport is well-defined for all points of $B$, we can shrink the rescaling parameter in (4.15) to zero and thereby isotope $h_{\sigma_i}^{res}$ to $h_{\sigma_i}$. Let $kTL$ and $lT'm$ be tangles, $\sigma_i^+, \sigma_i^- \in Br_{2l}$ elementary braids and $T^\pm = T\sigma_i^\pm T'$. We observe that if $a$ and $b$ are crossingless matchings and we take
\( L = (a^t, \Phi(T)) \) and \( L' = (\Phi(T'), b^t) \) then the map \( f \) in (7.27) is the same as the cobordism map (7.13).

**Theorem 7.6.5.** Let \( e \) be the difference between the number of negative crossings in \( TT' \) and \( T \cup_i \cap_i T' \) (with the latter oriented arbitrarily). Then \( \text{CSS}(T^-) \) is quasi-isomorphic to the cone of

\[
\text{CSS}(T \cup_i \cap_i T') \{1 - 2e\} \xrightarrow{\text{CSS}(1_{T \cup_i \cap_i T'})} \text{CSS}(TT') \quad (7.33)
\]

and \( \text{CSS}(T^+) \) is quasi-isomorphic to the cone of

\[
\text{CSS}(TT') \{-1\} \xrightarrow{\text{CSS}(1_{T \cup_i \cap_i T'})} \text{CSS}(T \cup_i \cap_i T') \{-2 - 2e\}. \quad (7.34)
\]

**Proof.** We note that the sign conventions for positive braids and positive Dehn twists are opposites of each other. Since the degree of the map (7.13) equals 1, we apply the degree shift \( \{-1\} \) to its target to obtain a map of degree zero. We have \( w(T^-) = w(TT') - 1 = w(T \cup_i \cap_i T') + 2e - 1 \) so we obtain (7.33).

In this case of \( T^+ \) we have \( w(T^+) = w(TT') + 1 = w(T \cup_i \cap_i T') + 2e + 1 \) and the cobordism map is of degree 1.

We have the following diagrams.

\[
\begin{array}{ccc}
\text{CSS}(T^-) & \xrightarrow{\{1\}} & \text{CSS}(TT') \\
\text{CSS}(T \cup_i \cap_i T') \{1 - 2e\} & \xrightarrow{\text{CSS}(1_{T \cup_i \cap_i T'})} & \text{CSS}(TT') \\
\end{array}
\]

\[
\begin{array}{ccc}
\text{CSS}(T^+) & \xrightarrow{\{1\}} & \text{CSS}(T \cup_i \cap_i T') \{-2 - 2e\} \\
\text{CSS}(TT') \{-1\} & \xrightarrow{\text{CSS}(1_{T \cup_i \cap_i T'})} & \text{CSS}(T \cup_i \cap_i T') \{-2 - 2e\} \\
\end{array}
\]

These exact triangles are the same as those for Khovanov homology after the collapse of the bigrading as described in [19].
