# ABSTRACT OF THE THESIS 

Vendor Financing and Its Impact on Vendor's Optimal Policies<br>By JOSE BENEDICTO B. DUHAYLONGSOD

Thesis Directors:
DR. BENJAMIN MELAMED
DR. BEN SOPRANZETTI

This research aims to elucidate how vendor financing impacts the business strategy of the vendor and to shed light on the resulting optimal inventory and dividend policies. We consider a vendor employing a Make-to-Stock inventory policy and selling to a particular set of buyers facing product demand. The vendor is constrained by a fixed amount of capital available for purchasing inventory and incurs a variety of costs. Since the buyers are also financially constrained, the vendor offers financing to the buyers in the form of trade credits, and receives the corresponding incremental orders, which would not be placed with the vendor in the absence of vendor financing. This thesis makes two primary contributions: (1) the suboptimal supply chain policies that arise from implementing vendor financing are explored; and (2) a stochastic optimization model and the attendant objective function from the perspective of the vendor are formulated and solved for optimal financial and inventory policies, simultaneously. The objective function maximizes the expected discounted dividends generated by the vendor, given its initial inventory and capital, subject to capital constraints. This is compared and contrasted with the case wherein the vendor utilizes an inventory policy, but no vendor financing and cases wherein the vendor uses vendor financing but has less available access to external funds. Analyses and insights are provided thereafter.

## ACKNOWLEDGEMENTS

I would like to express my deep gratitude to Dr. Benjamin Melamed and Dr. Ben Sopranzetti, my thesis advisers, for their contribution, guidance, and invaluable critiques of this research.

I would also like to extend my special thanks Pedro Pontes, Paolo Trinidad and Joonhee Lee for their help in offering resources and support during my semesters here in the US.

Finally, I wish to thank my family, especially my mother, for the unwavering support, encouragement and belief in me throughout the course of my study.

## 1. Introduction

Vendor financing is the practice of vendors serving as monetary intermediaries that fund customer purchases in lieu of a bank or financial institution. A case in point took place in early 2000, when Motorola, one of the major telecommunication manufacturers in the US, extended vendor financing of close to $\$ 2$ billion to TelSim, a privately owned Turkish telecommunications provider. This was part of Motorola's initial growth strategy to enter emerging markets as the telecommunications industry was booming in the late 1990's. However, the political and economic instability in Turkey took a toll on TelSim and led the company to default on the $\$ 728$ million it owned Motorola on April 30, 2001.

This research aims to elucidate how vendor financing impacts the business strategy of the vendor and to shed light on the resulting optimal inventory and dividend policies. We consider a vendor employing a Make-to-Stock inventory policy and selling to a particular set of buyers (or end-customers) facing product demand. The vendor is constrained by a fixed amount of capital available for purchasing inventory and incurs a variety of costs. The vendor firm's corporate treasury manages all its financial transactions. Since the buyers are also financially constrained, the vendor offers financing to the buyers in the form of trade credits, and receives the corresponding incremental orders, which would not be placed with the vendor in the absence of vendor financing.

Vendor financing is a ubiquitous and important source of short-term working capital in the United States (Rajan \& Petersen 1997), in European markets (Wlison \& Summers 2002) and in less developed countries (Fisman \& Love 2003). Basically, in vendor financing (or trade credits), the vendor assumes the role of a typical financial institution and provides funding for a buyer that is unable to gain access to external funds due to its credit worthiness. The vendor typically enjoys a cost advantage over banks due to the following reasons: (a) ability to get more information on the buyer; (b) ability to exert control over the buyers in terms of
operations and production; (c) ability to carry out better salvaging and reselling of unsold products in cases of buyer defaults; and (d) ability to price discriminate among customers and reduce transaction costs. For buyers, the choice of vendor financing essentially stems from the bank's unwillingness to provide credit to a risky firm. Further, empirical evidence shows that optimal trade credit contracts are generally cheaper as compared to bank financing (Kouvelis \& Zhao 2012), and that small firms in financial distress gain a degree of security and safety when associating with a vendor that provides financing (Evans \& Koch 2007).

Vendor decisions to extend financing are primarily motivated by increased vendor sales, based on price discrimination among their buyers (Brennan, Maksimovic \& Zechner 1988), or by their subsequent ability to exert a measure of control over buyers (Rajan \& Petersen 1997). However, there is a dearth of literature addressing the effects and implications of vendor financing to the policies and financial performance of the vendor. Offering vendor financing would tie up the vendor's limited capital, and consequently, increase its chance of bankruptcy. But a more exigent issue arises when credit limits are ignored - an apparent resultant sub-optimality of the vendor's supply chain policies.

This paper is motivated by the observation that to attain global optimization, one should integrate and optimize logistics performance and financial performance simultaneously. Under such an integrated framework, the focal party is a vendor firm which must balance and optimize the conflicting goals of revenue enhancement and lending risk, subject to capital availability. Vendor financing enhances revenue as incremental demand is added in the form of financed sales that might otherwise be delayed or lost. The downside of vendor financing is that the vendor's capital is tied up and encumbered by lending risk. For the vendor to generate the same incremental sales, it might have to consider external financing
to supplement limited internal capital, but external financing is typically a more expensive source of capital, thereby increasing bankruptcy risk.

As the vendor assumes the role of a lender in this financing scheme, the following questions arise:

1. How does the vendor's decision to offer vendor financing impact operational decisions, such as optimal inventory and dividend policies?
2. Does vendor financing augment the baseline demand it initially faces?
3. Are there any unintended consequences stemming from the vendor's decision to extend financing?

This thesis makes two primary contributions to the literature. Firstly, we explore the suboptimal supply chain policies that arise from implementing vendor financing. This results from the tension between the increased revenue generated by the vendor due to its decision to offer vendor financing and the concomitant reduction in capital available to implement inventory policies. Secondly, we formulate a stochastic optimization model and the attendant objective function from the perspective of the vendor, and solve for optimal financial and inventory policies, simultaneously. More specifically, our objective function aims to optimize the vendor's stock price by maximizing the total expected discounted dividends generated by the vendor, given its initial inventory and available capital, subject to capital constraints. This is later compared and contrasted with the following scenarios: (1) case wherein the vendor utilizes an inventory policy, but no vendor financing; and (2) cases wherein the vendor uses vendor financing but has less available access to external funds.

We shall use the following notation. For any real $x, x^{+}=\max \{x, 0\}$ and $x^{-}=\min \{x, 0\}$.

This thesis is organized as follows. Section 2 contains a literature review. Sections 3 and 4 discuss, respectively, the conceptual description of the system considered and mathematical model formulation. Section 5 solves the combined inventory and financial optimization problem and presents the results and analysis. Finally, Section 6 provides the conclusion of the thesis and offers insights.

## 2. Literature Review

### 2.1 Vendor Financing

The literature of vendor financing can be divided into two categories: (1) reasons for vendors and buyers to utilize vendor financing; and (2) mathematical models thereof.

The apparent advantages of vendor financing to both vendor and buyer have been treated in numerous publications. The most referenced paper appears to be Rajan \& Petersen (1997), which includes an extensive review and empirical study of the reasons that underlie vendor financing. The paper posits a number of conjectures, based on empirical evidence, such as the vendor's ability to capture and hold onto future business prospects if it provides credit to buyers and acquires industry information at lower costs.

Vicente Cuñat (2006) argues that the rise of vendor financing in the competitive banking sector is a natural result of interactions among buyers and vendors. More specifically, vendors are in a better position to demand debt repayment from buyers as compared to a bank due to the control the vendors exert over the supply of specific intermediate goods, and this specificity makes substitution expensive for the buyer. Consequently, vendors provide liquidity to their buyers when these buyers encounter liquidity problems or when losing buyers is overly costly. The paper further points out that the level of trade credit builds up as time goes by and as the relationship between buyer and vendor moves forward, typically accompanied by increasing sales volumes and trust. Finally, the paper provides empirical results that exhibit the usage of trade credit as a form of financing of last resort.

Fabbri and Klapper (2011) posits two hypotheses regarding what motivates a vendor to extend trade credits to its buyers. First, the paper opines that vendors offer financing to their buyers as a competitive gesture due to weak vendors' market power or the presence of a high degree of competition in the market. This motivates the provision of better credit terms to
buyers and subsequent increase of sales on credit. Second, the paper states that vendors offer trade credits similar to the amount and terms they receive from their suppliers. The paper points out that a vendor utilizes the payables as a means to manage risk as it matches its payables and receivables terms.

Several publications model vendor financing from the perspective of the vendor under different assumptions, and offer explanations for opting for vendor financing. Brennan, Maksimovic and Zechner (1988) proposes an optimization framework for analyzing the optimality of vendor financing from the perspective of a monopolistic vendor. Optimality is attained through product price discrimination when there is evident discrepancy in the reservation prices of cash and credit buyers or when there is asymmetric information among supply chain members that precludes customized contracts for buyers with different credit risks, even in a perfectly competitive banking environment. The model is extended to oligopolistic markets where optimality is retained due to the fact that vendor financing can reduce competition among vendors. Although this paper aims to maximize profit, it does not constrain the vendor's initial capital and ignores tying up of capital in lending transactions. It does not address the optimal inventory policy as it assumes that the vendor is always able to fulfill the demand of its buyers.

Kouvelis and Zhao (2012) constructs a model that assumes a newsvendor setting of a buyer and a vendor, both of which are capital constrained and subject to bankruptcy risk. The paper identifies the optimal supply contract (optimal wholesale price and interest rate) using a game theoretic-approach (Stackelberg Game). Here, a financially constrained buyer (e.g., one that has limited access to financing due to low credit worthiness) would prefer vendor financing over bank financing. The reason is that vendor financing ultimately improves the efficiency of the supply chain by giving rise to more orders from buyers, which in turn increases overall profitability. The model closely resembles ours in that it takes into
consideration vendor capital and inventory decisions. However, the paper focuses more on modeling the strategic interactions between buyer and vendor to derive the optimal supply contract.

Wang (2011) presents another examination of vendor financing and other financing schemes, all from the vendor's viewpoint. It uses a Stackelberg Game approach to model and characterize the performance of supply chain members under three financing schemes: independent financing, vendor financing and inventory subsidy. It then compares the effects of these practices on various performance metrics, such as profits, wholesale price, expected sales volume, etc., and clarifies the selection and implementation of financial arrangements. The paper also shows that buyer and vendor preferences for vendor financing depend on whether the vendor's cost of capital is below that of the buyer's. These results are shown to be robust with respect to certain assumptions on the demand distribution.

### 2.2 Stochastic Programming - Solution Quality Assessment

Optimality conditions of solutions are essential ingredients of optimization. In particular, tests for assessing the nearness to optimality of a given solution generally have a higher computational complexity in the context of stochastic programming because of the experimental error induced by random variables, and the need to use approximation methods to solve some of these problems [8, 9].

Bayraksan and Morton (2006) presents four Monte-Carlo sampling-based procedures to assess a solution obtained from approximation methods for solving stochastic programming problems. The stochastic programming problem considered there is

$$
\begin{equation*}
z^{*}=\min _{x \in X} \mathbb{E}[f(x, \Xi)] \tag{2.1}
\end{equation*}
$$

where $f$ is a real-valued objective function, $x$ is the decision vector, $\Xi$ is a random vector whose distribution is known, $X \in \mathbb{R}^{d}$ is the set of constraints and $z^{*}$ is the optimal value of (2.1). A sampling-based approximation for the model is given by

$$
\begin{equation*}
Z_{n}^{*}=\min _{x \in X} \frac{1}{n} \sum_{i=1}^{n} f\left(x, \xi_{i}\right) \tag{2.2}
\end{equation*}
$$

where the $\xi_{i}$ have the same distribution as $\Xi$ and the $Z_{n}^{*}$ is the optimal value of (2.2). The optimal solution of (2.2) is denoted as $x_{n}^{*}$. This sampling and approximation approach is used when the dimension of the random vector $\Xi$ is very large and the exact solution of (2.1) becomes too difficult to obtain. The asymptotic correctness of the solution estimate obtained from (2.2) has been discussed extensively in various other literatures (referenced in [1, 2]).

The following assumptions are made regarding the stochastic programming problem:
(1) $f(., \Xi)$ is continuous on $X$, with probability one
(2) $\mathbb{E}\left[\sup _{x \in X} f^{2}(x, \Xi)\right]<0$
(3) $X \neq \emptyset$ and is a compact set

The test procedures are based on the idea of using the optimality gap of a given estimated solution $\hat{x}$, namely,

$$
\begin{equation*}
\mu_{\hat{x},}=\mathbb{E}[f(\hat{x}, \Xi)]-z^{*} \tag{2.3}
\end{equation*}
$$

as a measure of quality of the solution. A sufficiently small gap implies that $\hat{x}$ is near optimal. Since exact computation of $\mathbb{E}[f(\hat{x}, \Xi)]$ and $z^{*}$ is difficult, we merely estimate an upper bound of the optimality gap, given by $\mathbb{E}[f(\hat{x}, \Xi)]-\mathbb{E}\left[Z_{n}^{*}\right]$. This is obtained from the derived statistical lower bound of $z^{*}, \mathbb{E}\left[Z_{n}^{*}\right]$, and the upper bound of $z^{*}, \mathbb{E}[f(\hat{x}, \Xi)]$, due to the general suboptimality of $\hat{x}$. The upper bound for the optimality gap is estimated by

$$
g_{n}(\hat{x})=\frac{1}{n} \sum_{i=1}^{n} f\left(\hat{x}, \xi_{i}\right)-\min _{x \in X} \frac{1}{n} \sum_{i=1}^{n} f\left(x, \xi_{i}\right)
$$

The first term of $g_{n}(\hat{x})$ converges to $\mathbb{E}[f(\hat{x}, \Xi)]$ by the Strong Law Of Large Numbers with probability 1 , and the second term is a lower bound estimate of $z^{*}$. Using these estimates, a one-sided $100(1-\alpha) \%$ confidence interval on the estimated optimality gap is constructed via four procedures described in the paper: Multiple Replications Procedure (MRP), Single Replication Procedure (SRP), Independent 2-Replication Procedure (I2RP) and Averaged Two-Replication Procedure (A2RP). The first has been presented in an earlier publication [12], while the remaining three are discussed in this paper. The last two procedures are variants of SRP.

The methodology underlying the four procedures above is similar. One starts with an estimated solution, $\hat{x}$, to be assessed for optimality. Next, one samples a vector $\xi_{i}$ from the known random vector $\Xi$, which are used in turn to solve (2.2). With the solution obtained from (2.2) and the estimated solution $\hat{x}$, one constructs the estimated gap, sample variance $\left(s_{n}^{2}\right)$ and a one-sided confidence interval, using Student's t -distribution with $n$ degrees of freedom and prescribed confidence level, $100(1-\alpha) \%$. The four procedures differ in their sampling methods, number of simulation replications, and formulae for the estimated gap and sample variance. Finally, the paper provides numerical examples (Newsvendor Problem and Two-Stage Stochastic Programming Problem). It also describes potential problems and guidelines for improving the performance of the procedures. Refer to [1] for the detailed steps of each procedure.

## 3. Conceptual Model

We consider a vendor employing a Make-to-Stock (MTS) inventory policy and selling to a particular set of buyers. The vendor is constrained by a prescribed initial amount of capital available for purchasing inventory and paying other costs, and faces demands it wishes to satisfy. The vendor's corporate treasury manages all financial transactions. The interaction between the supply chain members extends over an infinite time horizon, divided into periods of equal lengths. Inventory and/or financial transactions take place at the boundary points of periods.

Figure 1 depicts schematically the system under consideration. It consists of a focal vendor firm that sells inventory to buyers, is replenished by a tier-1 supplier, is provided with external capital by a funding entity and disgorges dividends to its owners.

Figure 1. Schematic of a generic system utilizing vendor financing

Here, the focal vendor firm boundary is denoted by the dotted line, and the boxes inside it stand for the vendor's inventory and treasury components. These two components are joined
through interactions with external entities such as buyers, a tier-1 supplier (or supplier for short), a funding entity and the owners of the vendor. The solid arrows represent tangible flows, such as product and money, while the dashed arrows represent flows of information. The elements and rules of operation of the system are described as follows:

## Inventory operations

- Demand. The vendor faces random demand from buyers. Demand is filled at the end of the each period, subject to limited backordering, that is, the number of unfilled orders that could be carried over to the next period is constrained and the rest is lost. Furthermore, the vendor backorders only that portion of the demand shortfall that can be funded at the time of backordering. This backorder quantity is fulfilled (here, defined as delivered to the buyer and paid for by the buyer) at the end of the next period and is funded first before any newly-arrived demand in that period. Any unfilled backorders are carried over to the next period.
- Replenishment. At the beginning of each period, the vendor orders inventory for replenishment through a supplier with unlimited capacity. However, there is a 1 period lead time, that is, the actual delivery occurs at the end of the period. The vendor's replenishment order is computed to bring the inventory level as close as possible (funding permitting) to the prescribed MTS base stock level. Orders are financed by first utilizing the vendor's cash on hand, and if insufficient, the balance is financed by debt, which is interest-bearing. The unit cost of ordered product is less than the unit selling price of the product.

## Financial operations

- Net Cash. The vendor's net cash is the difference between its cash on hand and its debt. Consistent with the Myers and Majluf (1984) Pecking Order theory, the firm will first use cash on hand to fund inventory and then debt. Consequently, if there is
any debt outstanding, the firm will immediately use any cash on hand to retire as much of it as possible. As a result, cash on hand and debt are mutually exclusive of one another. The net cash, if positive, earns interest for the previous period, and if negative, pays interest for the previous period.
- Financing of Buyers Purchases. Buyers are able to self-fund demand up to a level, which represents the buyers' bank-extended credit limit. Self-funded demand is paid for by the buyers immediately. Any demand above this trade credit limit but less than a vendor-determined threshold (called the vendor-extended credit limit) is financed by the vendor. In all purchases, the buyers' bank-extended credit limit is used up first before dipping into the buyers' vendor-extended credit limit. This vendor financing is in the form of 1-period loans (secured by the purchased goods), each of which is repaid in a lump sum at the end of the respective period plus interest. The interest rate charged by the vendor is higher than the vendor's cost of financing (described below).
- Financing of Vendor Operations. The vendor cannot sell additional equity, but has access to external debt capital, subject to a credit limit, called the vendorborrowing credit limit. If the vendor does not have enough cash on hand to pay for an order, it will borrow at most the amount needed to cover the cost of the MTSbased order, subject to the vendor-borrowing credit limit. This type of borrowing will be referred to as vendor minimal borrowing.
- Dividend Payout. All cash exceeding a certain threshold, called the dividend threshold, is distributed to the vendor's shareholders as dividends at the end of each period. Dividends are paid only from the vendor's cash on hand only after all other liabilities are satisfied. It is assumed that the vendor pays out dividends first to the shareholders before checking its inventory level and issuing the replenishment order for the next period.
- Vendor Bankruptcy. Bankruptcy occurs at period boundary points whenever vendor resources (the vendor's current cash position plus credit limit plus liquidation value of the vendor's inventory) are insufficient to cover outstanding costs. In the event of bankruptcy, the vendor is liquidated, and otherwise, operations continue (see Section 4 for details).

In our model, the decision variables of the optimal policy are the MTS base stock level and dividend threshold. The goal of the thesis is to identify the optimal policy in terms of these decision variables that maximizes the total expected discounted dividends of the vendor, given its initial inventory and capital and subject to its capital constraints. The optimal MTS policy with vendor financing will be compared and contrasted with: (1) the optimal policy of a vendor employing MTS but offering no vendor financing; and (2) the optimal policy with vendor financing but the vendor has a smaller credit limit.

## 4. Mathematical Model

In this section, we formulate the mathematical model and establish our notation. The infinite time horizon $\cup_{i=1}^{\infty}\left(\tau_{i-1}, \tau_{i}\right]$ is divided into equally-spaced periods, where $\left(\tau_{i-1}, \tau_{i}\right.$ ] denotes period $i$, the $\tau_{i}$ are the period boundary points, and $\tau_{0}=0$.

The model uses the following parameters:

- $e_{0}>0$ is the initial cash on hand provided by the owners of the vendor.
- $u_{0}>0$ is the initial size of the vendor's inventory.
- $r_{e}>0$ is the simple earned interest rate on the vendor's cash on hand over each period.
- $r_{b}>0$ is the interest rate paid by the buyers to the vendor.
- $r_{v}>0$ is the interest rate paid by the vendor to the funding entity. We assume $r_{e}<r_{v}<r_{b}$.
- $K$ is the fixed cost incurred by the vendor for each period.
- $c>0$ is the unit cost of ordered product by the vendor.
- $p_{s}>0$ is the unit price of product sold by the vendor. We assume that $c<p_{s}$.
- $p_{f}>0$ is the unit price of forced-sale product. We assume that $p_{f}<p_{s}$.
- $h>0$ is the inventory holding cost per unit inventory per period.
- $g>0$ is the backordering penalty cost per unit of backordered inventory per period.
- $G_{v}>0$ is the vendor-borrowing credit limit of the vendor when borrowing from the funding entity.
- $G_{b}>0$ is the vendor-extended credit limit of the buyers when borrowing from the vendor
- $H_{b}>0$ is the buyers' bank-extended credit limit.
- $B_{\max }>0$ is the maximal number of backorders. Any orders beyond this value are lost.
- $0<\beta<1$ is the discount factor per period.

The exogenous source of randomness is the i.i.d. demand process $\left\{D_{i}: i \geq 0\right\}$, where $D_{i}$ is the demand size in period $i$ with the convention $D_{0}=0$. The value of the $D_{i}$ becomes known at $\tau_{i}$.

The random processes derived from the exogenous one are defined as follows:

- $\left\{X_{i}: i \geq 0\right\}$ denotes the inventory-size process, where $X_{i}$ is the vendor's ending inventory at $\tau_{i}$.
- $\left\{Z_{i}: i \geq 0\right\}$ denotes the inventory order process, where $Z_{i}$ is the number of units ordered by the vendor at $\tau_{i}$.
- $\left\{R_{i}: i \geq 1\right\}$ denotes the period revenue process, where $R_{i}$ is the number of units sold by the vendor multiplied by the unit price of product sold at $\tau_{i}$.
- $\left\{C_{i}: i \geq 0\right\}$ denotes the ending cash process, where $C_{i}$ is the vendor's ending cash balance at $\tau_{i}$. Accordingly, $C_{i}=C_{i}^{+}+C_{i}^{-}$, where $C_{i}^{+}$and $C_{i}^{-}$are the corresponding vendor's cash on hand and outstanding debt balance, respectively.
- $\left\{V_{i}: i \geq 1\right\}$ denotes the dividends process, where $V_{i}$ is the amount of dividends paid out (if any) by the vendor at $\tau_{i}$.

The decision variables of the vendor are as follows.

- $S \geq 0$ denotes the MTS base stock level, which characterizes the inventory policy.
- $T \geq 0$ denotes the dividend threshold which characterizes the dividend policy.

The evolution of the MTS system is described in terms of a state process $\left\{S_{i}: i \geq 0\right\}$, where the state at $\tau_{i}$ is given by

$$
\begin{equation*}
S_{i}=\left(X_{i}, C_{i}, D_{i}\right), \tag{4.1}
\end{equation*}
$$

Since the third component above is exogenous, it suffices to describe the system's evolution in terms of the first two components only.

### 4.1 Mathematical Model with Vendor Financing

Following are the state transitions for the case of vendor financing:

1. Initialization at time $\boldsymbol{\tau}_{\mathbf{0}}=\mathbf{0}$. The system starts with initial cash on hand $e_{0}$ and initial inventory $u_{0}$. The following transactions are carried out:
2. Let

$$
\begin{aligned}
X_{0} & =u_{0} \\
C_{0} & =e_{0}
\end{aligned}
$$

2. Let

$$
L_{0}^{(v)}=\min \left\{\left[c\left(S-X_{0}\right)-C_{0}\right]^{+}, G_{v}\right\}
$$

where $L_{0}^{(v)}$ is the initial loan (if any) borrowed by the vendor from the funding entity. The equation above follows from the inequalities

$$
L_{0}^{(v)} \leq\left[c\left(S-X_{0}\right)-C_{0}\right]^{+} \text {and } L_{0}^{(v)} \leq G_{v}
$$

3. Finally, let

$$
Z_{0}=\min \left\{\left[S-X_{0}\right]^{+}, \frac{L_{0}^{(v)}+C_{0}}{c}\right\}
$$

The equation above follows from the inequalities

$$
Z_{0} \leq\left[S-X_{0}\right]^{+} \text {and } Z_{0} \leq \frac{L_{0}^{(v)}+c_{0}}{c}
$$

since the right hand side in the first inequality is the nominal MTS-based order size, while its counterpart in the second inequality is the order size the vendor can afford.

## B. State Transition to $\boldsymbol{\tau}_{1}=1$.

1. Let

$$
\begin{aligned}
& X_{1}^{(b)}=X_{0}+Z_{0} \\
& C_{1}^{(b)}=C_{0}-c Z_{0}
\end{aligned}
$$

where $X_{i}^{(b)}, i \geq 1$, is the vendor's intermediate inventory level after replenishment arrives at $\tau_{i}$ and $C_{i}^{(b)}, i \geq 1$, is the vendor's intermediate cash balance after subtracting the cost of that replenishment.
2. Let

$$
\begin{equation*}
D_{1}^{(f)}=\min \left\{D_{1}, \frac{H_{b}+G_{b}}{p_{s}}\right\} \tag{4.2}
\end{equation*}
$$

where $D_{i}^{(f)}, i \geq 1$, is the total fundable demand that could be financed by the buyers through their bank-extended line of credit as well as any vendor-extended financing at $\tau_{i}$.
3. Let

$$
D_{1}^{(a t f)}=\min \left\{X_{1}^{(b)}, D_{1}\right\}
$$

where $D_{i}^{(a t f)}, i \geq 1$, is the portion of demand that is available for immediate fulfillment from the vendor's inventory on hand at $\tau_{i}$.
4. Let

$$
\begin{gather*}
D_{1}^{(b f)}=\min \left\{D_{1}^{(a t f)}, \frac{H_{b}}{p_{s}}\right\} \\
D_{1}^{(v f)}=\min \left\{D_{1}^{(a t f)}-D_{1}^{(b f)}, \frac{G_{b}}{p_{s}}\right\} \tag{4.3}
\end{gather*}
$$

where $D_{i}^{(b f)}, i \geq 1$, is the portion of $D_{i}$ that is actually financed by the buyers at $\tau_{i}$, and $D_{i}^{(v f)}, i \geq 1$, is the portion of $D_{i}$ that is actually financed by the vendor at $\tau_{i}$. Note that the sum, $D_{i}^{(b f)}+D_{i}^{(v f)}$, is the amount of demand actually fulfilled at $\tau_{i}$.
5. Let

$$
\begin{equation*}
D_{1}^{(b o)}=\min \left\{D_{1}^{(f)}-\left(D_{1}^{(b f)}+D_{1}^{(v f)}\right), B_{\max }\right\} \tag{4.4}
\end{equation*}
$$

where $D_{i}^{(b o)}, i \geq 1$, is the portion of $D_{i}$ that is actually backordered by the vendor at $\tau_{i}$.
6. Let

$$
\begin{equation*}
X_{1}^{(a)}=X_{1}^{(b)}-\left(D_{1}^{(b f)}+D_{1}^{(v f)}\right)-D_{1}^{(b o)} \tag{4.5}
\end{equation*}
$$

where $X_{i}^{(d)}, i \geq 1$, is vendor's intermediate inventory level after subtracting fulfillment (if any) and backorders (if any) at $\tau_{i}$.
7. Let

$$
\begin{equation*}
L_{1}^{(b)}=p_{s} D_{1}^{(v f)} \tag{4.6}
\end{equation*}
$$

where $L_{i}^{(b)}, i \geq 1$, is the loan (if any) extended by the vendor to the buyers at $\tau_{i}$.
8. Let

$$
R_{1}=p_{s} D_{1}^{(b f)}
$$

9. Let

$$
C_{1}^{(d)}=C_{1}^{(b)}-\left[h W_{1}+K+g D_{1}^{(b o)}+r_{v} L_{0}^{(v)}\right]+\left[R_{1}+r_{e} C_{0}^{+}\right]
$$

where $C_{i}^{(d)}, i \geq 1$, is the intermediate cash after subtracting period costs and penalties (holding and fixed costs, backordering penalties and interest owed) and adding period earnings (revenue from fulfilled demand and interest(s) earned) and $W_{i}=\frac{X_{i-1}^{+}+\left[X_{i}^{(d)}\right]^{+}}{2}, i \geq 1$, is an approximate inventory time average over period $i$.
10. Let the vendor's bankruptcy condition be given by

$$
C_{1}^{(d)}+G_{v}+p_{f}\left[X_{1}^{(d)}\right]^{+}<0
$$

Namely, the sum of the vendor's resources (intermediate cash, vendor's credit limit, and the liquidation value of vendor's inventory on hand) is negative. If this condition holds, then the vendor declares bankruptcy, and the system transitions to an absorbing state. Otherwise, operations continue.
11. Let

$$
X_{1}^{(s)}=\frac{-\left[C_{1}^{(d)}+G_{v}\right]^{-}}{p_{f}}
$$

where $X_{i}^{(s)}, i \geq 1$, is the minimal forced-sale portion of $X_{1}^{(d)}$ that raises just enough funds to avoid bankruptcy (that is, to cover debt in excess of the vendor's credit limit) at $\tau_{i}$.
12. Let

$$
V_{1}=\left[C_{1}^{(d)}-T\right]^{+}
$$

13. Let

$$
\begin{gathered}
X_{1}=X_{1}^{(d)}-X_{1}^{(s)} \\
C_{1}=\left(C_{1}^{(d)}+p_{f} X_{1}^{(s)}\right)-V_{1}
\end{gathered}
$$

14. Let

$$
L_{1}^{(v)}= \begin{cases}0, & \text { if } c\left(S-X_{1}\right) \leq C_{1} \\ \min \left[c\left(S-X_{1}\right)-C_{1}, G_{v}\right], & \text { if } 0<C_{1}<c\left(S-X_{1}\right) \\ \min \left[c\left(S-X_{1}\right), G_{v}+C_{1}\right], & \text { if }-G_{v}<C_{1} \leq 0 \\ 0, & \text { if } C_{1} \leq-G_{v}\end{cases}
$$

where $L_{i}^{(v)}, i \geq 1$, is the loan (if any) borrowed by the vendor from the funding entity at $\tau_{i}$.
15. Let

$$
Z_{1}=\min \left\{\left[S-X_{1}\right]^{+}, \frac{L_{1}^{(v)}+C_{1}^{+}}{c}\right\}
$$

This equation follows from the inequalities $Z_{i} \leq\left[S-X_{1}\right]^{+}$and $Z_{i} \leq \frac{L_{i}^{(v)}+C_{1}^{+}}{c}$, since the right hand side in the first inequality is the nominal MTS-based order size, while its counterpart in the second inequality is the order size the vendor can fund.
16. Finally, let

$$
B_{1}^{(d)}=\min \left\{-X_{1}^{-}, Z_{1}\right\}
$$

where $B_{i}^{(d)}, i \geq 1$, is portion of the backorder quantity that could be fulfilled by the order $Z_{i}$ which arrives as replenishment at $\tau_{i+1}$.

## C. State Transition to $\boldsymbol{\tau}_{i}, \boldsymbol{i} \geq \mathbf{2}$.

1. Let

$$
\begin{aligned}
X_{i}^{(b)} & =X_{i-1}+Z_{i-1} \\
C_{i}^{(b)} & =C_{i-1}-c Z_{i-1}
\end{aligned}
$$

2. Let

$$
\begin{equation*}
D_{i}^{(f)}=\min \left\{D_{i},\left[\frac{H_{b}+\left(G_{b}-L_{i-1}^{(b)}\right)}{p_{s}}-B_{i-1}^{(d)}\right]^{+}\right\} \tag{4.7}
\end{equation*}
$$

Recall that funding backorders from the previous period takes precedence over any newly-arrived demand in the current period.
3. Let

$$
D_{i}^{(a t f)}=\min \left\{\left[X_{i}^{(b)}\right]^{+}, D_{i}\right\}
$$

Note that if there are still unfilled backorders after replenishment, that is, $X_{i}^{(b)}<0$, then the vendor has no available inventory for immediate fulfillment of new demand.
4. Let

$$
\begin{gather*}
D_{i}^{(b f)}=\min \left\{D_{i}^{(a t f)},\left[\frac{H_{b}}{p_{s}}-B_{i-1}^{(d)}\right]^{+}\right\} \\
D_{i}^{(v f)}=\min \left\{D_{i}^{(a t f)}-D_{i}^{(b f)}, \frac{\left(G_{b}-L_{i-1}^{(b)}\right)}{p_{s}}+\left[\frac{H_{b}}{p_{s}}-B_{i-1}^{(d)}\right]^{-}\right\} \tag{4.8}
\end{gather*}
$$

where we use the funds pecking order of Section 3 in the equations above, that is, the buyer uses its credit line with the bank before any vendor-extended credit, which is more expensive.
5. Let

$$
\begin{equation*}
D_{i}^{(b o)}=\min \left\{D_{i}^{(f)}-\left(D_{i}^{(b f)}+D_{i}^{(v f)}\right), B_{\max }+\left[X_{i}^{(b)}\right]^{-}\right\} \tag{4.9}
\end{equation*}
$$

This equation follows from the fact that any unfilled backorders are carried over to the next period (recall from Section 3), so the maximum amount that the vendor can backorder for the current period is $B_{\max }+\left[X_{i}^{(b)}\right]^{-}$, where $\left[X_{i}^{(b)}\right]^{-}$is the unfilled backorders from period $i-1$.
6. Let

$$
\begin{equation*}
X_{i}^{(d)}=X_{i}^{(b)}-\left(D_{i}^{(b f)}+D_{i}^{(v f)}\right)-D_{i}^{(b o)} \tag{4.10}
\end{equation*}
$$

7. Let

$$
\begin{equation*}
L_{i}^{(b)}=p_{s} D_{i}^{(v f)} \tag{4.11}
\end{equation*}
$$

8. Let

$$
\begin{equation*}
R_{i}=p_{s}\left[D_{i}^{(b f)}+D_{i-1}^{(v f)}+B_{i-1}^{(d)}\right] \tag{4.12}
\end{equation*}
$$

Note that the revenue above includes payment for buyer-financed demand for the current period, the principal of the vendor financing from the previous period, and payment for the filled backorders that were rolled over from the previous period.
9. Let

$$
\begin{equation*}
C_{i}^{(d)}=C_{i}^{(b)}-\left[h W_{i}+K+g D_{i}^{(b o)}+r_{v}\left(-C_{i-1}^{-}+L_{i-1}^{(v)}\right)\right]+\left[R_{i}+r_{e} C_{i-1}^{+}+r_{b} L_{i-1}^{(b)}\right] \tag{4.13}
\end{equation*}
$$

Note that period costs and penalties include holding and fixed costs, backordering penalties and interest owed from the vendor's total outstanding debt, and period earnings include the previously computed revenue and the interest earned from vendor's cash on hand and vendor financing.
10. The vendor's bankruptcy condition,

$$
\begin{equation*}
C_{i}^{(d)}+G_{v}+p_{f}\left[X_{i}^{(d)}\right]^{+}<0 \tag{4.14}
\end{equation*}
$$

is checked. If this condition holds, then the vendor declares bankruptcy, and the system transitions to an absorbing state. Otherwise, operations continue.
11. Let

$$
X_{i}^{(s)}=\frac{-\left[C_{i}^{(d)}+G_{v}\right]^{-}}{p_{f}}
$$

12. Let

$$
V_{i}=\left[C_{i}^{(d)}-T\right]^{+}
$$

13. Let

$$
\begin{gathered}
X_{i}=X_{i}^{(d)}-X_{i}^{(s)} \\
C_{i}=\left(C_{i}^{(d)}+p_{f} X_{i}^{(s)}\right)-V_{i}
\end{gathered}
$$

14. Let

$$
L_{i}^{(v)}= \begin{cases}0, & \text { if } c\left(S-X_{i}\right) \leq C_{i} \\ \min \left[c\left(S-X_{i}\right)-C_{i}, G_{v}\right], & \text { if } 0<C_{i}<c\left(S-X_{i}\right) \\ \min \left[c\left(S-X_{i}\right), G_{v}+C_{i}\right], & \text { if }-G_{v}<C_{i} \leq 0 \\ 0, & \text { if } C_{i} \leq-G_{v}\end{cases}
$$

15. Let

$$
Z_{i}=\min \left\{\left[S-X_{i}\right]^{+}, \frac{L_{i}^{(v)}+C_{i}^{+}}{c}\right\}
$$

16. Finally, let

$$
B_{i}^{(d)}=\min \left\{-X_{i}^{-}, Z_{i}\right\}
$$

Figure 2 summarizes the sequence of inventory and monetary transactions at each period boundary point. The columns of Figure 2 outline a series of transactions that take place at time at $\tau_{i}$ in the order of the vertical arrows. The horizontal arrow points to the contiguous period to which the transactions are associated with.

Figure 2. Outline of inventory and monetary transactions at period boundaries (with vendor financing) ${ }^{1}$

The objective function is the sum of the conditional expected discounted dividends paid out by the vendor over an infinite time horizon, given the initial inventory size and initial capital, that is,

$$
J(S, T)=\mathbb{E}\left[\sum_{i=1}^{\infty} \beta^{i} V_{i} \mid S_{0}=s_{0}\right]
$$

The goal is to find the optimal pair $\left(S^{*}, T^{*}\right)$ that optimizes the objective function above, yielding the optimal objective function value

$$
J^{*}=J\left(S^{*}, T^{*}\right)
$$

[^0]
### 4.2 Mathematical Model without Vendor Financing

The state transitions for the case of no vendor financing are the same as for the case of vendor financing but with the following exceptions:

Deletions. The following equations are not included:

1. Equation (4.3)
2. Equation (4.6)
3. Equation (4.8)
4. Equation (4.11)

Modifications. The following equations (and inequalities) are modified as follows:

1. Equation (4.2) becomes

$$
\begin{equation*}
D_{1}^{(f)}=\min \left\{D_{1}, \frac{H_{b}}{p_{s}}\right\} \tag{4.15}
\end{equation*}
$$

2. Equation (4.4) becomes

$$
\begin{equation*}
D_{1}^{(b o)}=\min \left\{D_{1}^{(f)}-D_{1}^{(b f)}, B_{\max }\right\} \tag{4.16}
\end{equation*}
$$

3. Equation (4.5) becomes

$$
\begin{equation*}
X_{1}^{(d)}=X_{1}^{(b)}-D_{1}^{(b f)}-D_{1}^{(b o)} \tag{4.17}
\end{equation*}
$$

4. Equation (4.7) becomes

$$
\begin{equation*}
D_{i}^{(f)}=\min \left\{D_{i},\left[\frac{H_{b}}{p_{s}}-B_{i-1}^{(d)}\right]^{+}\right\} \tag{4.18}
\end{equation*}
$$

5. Equation (4.9) becomes

$$
\begin{equation*}
D_{i}^{(b o)}=\min \left\{D_{i}^{(f)}-D_{i}^{(b f)}, B_{\max }+\left[X_{i}^{(b)}\right]^{-}\right\} \tag{4.19}
\end{equation*}
$$

6. Equation (4.10) becomes

$$
\begin{equation*}
X_{i}^{(d)}=X_{i}^{(b)}-D_{i}^{(b f)}-D_{i}^{(b o)} \tag{4.20}
\end{equation*}
$$

7. Equation (4.12) becomes

$$
\begin{equation*}
R_{i}=p_{s}\left[D_{i}^{(b f)}+B_{i-1}^{(d)}\right] \tag{4.21}
\end{equation*}
$$

8. Finally, equation (4.13) becomes

$$
\begin{equation*}
C_{i}^{(d)}=C_{i}^{(b)}-\left[h W_{i}+K+g D_{i}^{(b o)}+r_{v}\left(-C_{i-1}^{-}+L_{i-1}^{(v)}\right)\right]+\left[R_{i}+r_{e} C_{i-1}^{+}\right] \tag{4.22}
\end{equation*}
$$

Figure 3 summarizes the sequence of inventory and monetary transactions at each period boundary point. The columns of Figure 3 outline a series of transactions that take place at time at $\tau_{i}$ in the order of the vertical arrows. The horizontal arrow points to the contiguous period to which the transactions are associated with.

Figure 3. Outline of inventory and monetary transactions at period boundaries (no vendor financing) ${ }^{2}$

[^1]
## 5. Results and Analysis

This section describes the solution methodology, presents the results and provides an analysis thereof.

### 5.1 Methodology

This subsection describes the simulation-based optimization methodology used to obtain the optimal base stock level and dividend threshold, solution quality-assessment procedures, and approach to application of a naïve policy - a policy wherein there is no restriction or reduction in the baseline vendor-borrowing credit limit

First, eleven cases of the stochastic optimization model are considered and solved: 10 cases with vendor financing (called Case 1 through Case 10) and one case with no vendor financing (Case 11). The set of parameters used for all 11 cases are identical except for Case $2-10$, where vendor-borrowing credit limits differ, ranging from $90 \%$ to $10 \%$ of Case 1 . The Palisade Corporation's DecisionTools Suite - RiskOptimizer 5.5 [16] was used as an optimization tool. RiskOptimizer 5.5 uses Monte-Carlo simulation and Genetic Algorithm to generate random samples and optimize the decision variables. For each case, the optimization engine was run for over 2000 simulations (more than 2.5 hours per case). The summary logs of each optimization were included in the Appendix.

Second, three procedures were implemented to assess solution quality (as discussed in Section 2.2), namely, SRP, I2RP and A2RP. For each procedure, $N=200$ random samples were generated per replication to construct one-sided confidence intervals for the optimality gap (2.3) at confidence level $\alpha=0.05$. For variance reduction purposes [1], the same random samples were used in each procedure and each case. The Palisade Corporation's DecisionTools Suite - Evolver 5.5 [15] was used to solve the approximate stochastic problem (2.2) in each procedure and construct the aforementioned confidence intervals. The
computations involved in the construction of the confidence intervals (optimal gap estimate, sample variance etc.) in each case (as discussed in [1]) were included in the Appendix.

Finally, the optimal policy of Case 1 was applied to Case $6-10$ in other to gauge the suboptimality of the objective function values when a naïve policy was applied. A Monte-Carlo simulation (5000 iterations) was run for each case in order to compute random samples of the objective function. For each case, the resultant histogram of random objective function values and their respective mean, standard deviation and coefficient of variation were collected, as well as the percentage deviation from the optimal values. The Palisade Corporation's DecisionTools Suite - @Risk 5.5 [17] was used to run the Monte-Carlo simulations. The histograms were shown in the Appendix.

The following model parameters were used in all cases: 100 periods, $e_{0}=10, u_{0}=10$, $r_{e}=0.02, r_{b}=0.08, r_{v}=0.06, K=3, c=1, p_{s}=1.4, p_{f}=0.84, h=0.2, g=0.1, \quad G_{b}=12$, $H_{b}=10, B_{\max }=7, \beta=0.10$. Each demand process $\left\{D_{i}: i \geq 0\right\}$ was assumed to follow Poisson distribution with rate $\lambda=15$. Finally, $G_{v}=20$ was the baseline vendor-borrowing credit limit used in Case 1, with Case 2-10 using a decreasing percentage of this value.

### 5.2 Results

This subsection presents the results of the aforementioned optimization, solution assessment and simulation procedures.

Table 1 displays the results of the 11 cases: the optimal decision variables, $S^{*}$ and $T^{*}$, and the optimal objective function value, $J^{*}$, as well as the one-sided $95 \%$ confidence for the optimality gap for each case. Additionally, Figure 4 depicts the optimal decision variables and corresponding optimal objective function values as function of the vendor-borrowing credit limit.

|  | $\mathbf{S}^{*}$ | T** $^{*}$ | $\mathbf{J}^{*}$ | SRP CI | I2RP CI | A2RP CI |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Case 1 - with vendor financing | 11.418 | 0 | 22.633 | $[0.0,0.005]$ | $[0.0,0.005]$ | $[0.0,0.004]$ |
| Case 2 - with vendor financing <br> (90\% of Borrowing Credit Limit) | 11.428 | 0 | 22.660 | $[0.0,0.00007]$ | $[0.0,0.004]$ | $[0.0,0.002]$ |
| Case 3 - with vendor financing <br> (80\% of Borrowing Credit Limit) | 11.421 | 0 | 22.616 | $[0.0,0.002]$ | $[0.0,0.005]$ | $[0.0,0.003]$ |

| Case 11 - with no vendor financing | 7.143 | 0 | 16.244 | $[0.0,0.00004]$ | $[0.0,0.00004]$ | $[0.0,0.00004]$ |

Table 1. Optimization results and $95 \%$ confidence intervals for the optimality gap

Figure 4. Graph of the optimal decision variables and optimal objective values

The results of Table 1 and Figure 4 indicate that $S^{*}$ is generally constant in the vendorborrowing credit limit for cases with vendor financing. For $T^{*}$, Case $1-4$ have optimal values of 0 , but for Case $5-10$, the optimal values are positive and exhibit an increasing trend. For
$J^{*}$, the optimal values exhibit a gentle increasing trend for Case $1-5$ and a gentle decreasing trend for Case $6-10$. However, for Case $11, S^{*}$ and $J^{*}$, are significantly lower.

Table 2 displays the results when the optimal policy in Case 1 is applied to cases with $50 \%$ to $90 \%$ reductions in the vendor-borrowing credit limits (Case $6-10$ ). The values of $J^{*}$ are the mean of the resultant distributions from the aforementioned simulation runs. Table 2 also includes the standard deviation and coefficient of variation of these distributions and the percentage deviation from the initial values of $J^{*}$.

|  | Mean J* StandardDeviation Coefficient of Variation Percent Decrease |  |  |  |
| :---: | :---: | :---: | :--- | :---: |
| Case 6 - with vendor financing <br> (50\% of Borrowing Credit Limit) | 18.729 | 0.785 | 0.0419 | $19.49 \%$ |
| Case 7 - with vendor financing <br> (40\% of Borrowing Credit Limit) | 16.855 | 0.360 | 0.0214 | $26.70 \%$ |
| Case 8 - with vendor financing <br> (30\% of Borrowing Credit Limit) | 17.110 | 0.508 | 0.0297 | $24.32 \%$ |
| Case 9 - with vendor financing <br> (20\% of Borrowing CreditLimit) | 16.503 | 0.384 | 0.0233 | $25.96 \%$ |
| Case 10 - with vendor financing <br> $(\mathbf{1 0 \%}$ of Borroving CreditLimit) | 16.051 | 0.260 | 0.0162 | $26.60 \%$ |

Table 2. Suboptimal values of $J^{*}$ (Case 1 policy applied to Case 6 -10)

The results of Table 2 indicate that for Case $6-10$, there is at least a $19 \%$ decrease in $J^{*}$. Case 7 displays the largest percent decrease, while Case $8-10$ exhibit a gentle increasing trend.

### 5.3 Analysis

This subsection presents the analysis and discussion of the results in four parts: (1) assessment of the computed solutions; (2) comparison and contrast between vendor financing
and no vendor financing; (3) comparison and contrast of cases with vendor financing but with varying vendor-borrowing credit limit; and (4) implications of the applied naïve policy.

### 5.3.1 Assessment of Computed Solutions

The narrow-width confidence intervals for each case indicate that the computed solution $\left(S^{*}, T^{*}\right)$ are of high quality or near optimal, given the assigned confidence level of $95 \%$. Recall that the constructed confidence intervals are for the estimated upper bound of the optimality gap, defined in (2.3). Therefore, tight confidence intervals are good solution-quality assessors.

### 5.3.2 Vendor Financing vs. No Vendor Financing

We first consider the two extremal cases, Case 1 and 11, which correspond to vendor financing and no vendor financing, respectively. Contrasting the results in Table 1, we see that the two aforementioned cases differ dramatically in their values of $S^{*}$ and $J^{*}$. More specifically, Case 1 produced much larger values for $S^{*}$ and $J^{*}$ than Case 11 . These results highlight the primary effect of vendor financing - enhanced profits. With vendor financing, the vendor is able to finance the satisfaction of additional demand that would otherwise be lost. The vendor orders more inventory to capitalize on the additional demand and enjoys a higher gain in the process. However, when there is no vendor financing, the vendor only orders inventory to the extent that its buyers can afford.

We also observe an optimal dividend threshold of 0 for Case 1 and 11 . This result is in accordance with our objective of maximizing the total expected discounted dividends. With a discount factor of $\beta=0.10$, relatively cheap cost of capital (6\%) and no restriction on the vendor-borrowing credit limit, the vendor would be motivated to pay out more dividends so as to maintain a cash balance of 0 at the end of each period, and just borrow money to finance any orders for the next period.

### 5.3.3 Vendor Financing With Varying Vendor-Borrowing Credit Limit

Next, we consider the cases with vendor financing but with varying vendor-borrowing credit limits (Case $1-10$ ). We observe that the 10 cases produced values of $S^{*}$ that varied little, despite the diminishing vendor-borrowing credit limits.

Analyzing the results for $T^{*}$, we observe that Case $1-4$ yield an optimal value of 0 . This suggests that the reduced vendor-borrowing credit limit in these cases did not constitute binding constraints on vendor borrowing (that is, optimal vendor borrowing does not exceed its credit limit). Thus, the vendor is able to continue operations optimally while maintaining a zero cash balance at the end of each period. However, once these reductions in the vendorborrowing credit limit lower it sufficiently (as in Case $5-10$ ), the relative constancy of $S^{*}$ is accompanied by a higher value of $T^{*}$ to maintain optimality. Table 1 shows that the effect of reduced vendor-borrowing credit limit is more conspicuous in $T^{*}$ than in $S^{*}$.

We next consider the optimal policies for Case 5 - 10. As mentioned above, a higher reduction in the vendor-borrowing credit limit leads to a higher $T^{*}$, which drives the vendor to hoard some cash. Table 1 shows that this higher $T^{*}$ was accompanied by a small increase in $S^{*}$.

As mentioned before, to maintain optimality, reduction in the vendor-borrowing credit limit is accompanied by an increase in $T^{*}$. However, this increase in $T^{*}$ reduces the value of $J^{*}$, because less cash is allocated to dividends in each period. Table 1 shows how $T^{*}$ impacts $J^{*}$. On the other hand, the aforementioned gentle decreasing trend in $J^{*}$ implies that the vendor is still able to pay out relatively large dividends despite having very low credit limit.

The results of Table 1 highlight the tension between increased profits and extended vendor financing. The potential gain from vendor's enhanced profits is offset not only by delayed
payments from buyers but also by a diminishing vendor-borrowing credit limit. The vendor is forced to hold on to more cash due to delayed receivables from vendor financing and reduced borrowing power, which leads to lower dividend payouts.

### 5.3.4 Vendor Financing - Application of the Naïve Policy

Finally, we applied the naïve policy of Case 1 to Case 6 - 10 where the reduction in the vendor-borrowing credit limit diminishes $J^{*}$. The results of Table 2 show that applying this naïve policy give rise to suboptimal values of $J^{*}$ because the vendor disgorges more cash as dividends than optimality calls for. In the same table, we observe a higher percent decrease in Case 7 - 10 than in Case 6. We observed that in Case 7 - 10, higher reductions in the credit limit and deviations of the naïve policy from the optimal policy lead to a more substantial decrease of $J^{*}$.

The results of Table 2 demonstrate the consequences of deviating from the optimal policy by substituting for it the naïve one, thereby ignoring the effect of the vendor-borrowing credit limit. In such cases, the vendor's attempt to increase profitability by extending vendor financing to buyers is severely impacted by substantial reductions in the vendor-borrowing credit limit.

## 6. Conclusion

The published literature does not address vendor financing and its interaction with vendorborrowing credit limits. To fill this lacuna, we developed a detailed and realistic model of a vendor's inventory and treasury, subject to a joint supply/financial policy concerning optimal replenishment and optimal dividend distribution.

We found that vendor financing is beneficial as evidenced by the results of Section 5.2, but careful consideration of the financial capabilities of both the vendor and the buyers is called for. The results of Table 1 and 2 demonstrate the potential risks inherent in vendor financing in the presence of limited vendor-borrowing credit limits, as well as uncritical application of a naïve supply/finance policy. Our results underscore the importance of coordinating logistical and financial decisions to attain improved optimization of a supply chain performance.

To sum up, the following insights have been gleaned from our analysis of vendor financing:
(1) Vendor financing enhances profitability provided there is no substantial reduction in the vendor-borrowing credit limit.
(2) Higher reductions in the vendor-borrowing credit limit have a major impact on the optimal dividend threshold. In our model, the vendor maintains a particular optimal MTS base stock level, but simultaneously increases the optimal dividend threshold.
(3) Naïve inventory and dividend policies can yield substantially suboptimal dividend payouts, especially in the presence of substantial reductions in the vendor-borrowing credit limit.
