# ABSTRACT OF THE DISSERTATION 

# Slice Filtration and Torsion Theory in Motivic Cohomology 

by KNIGHT FU<br>Dissertation Director:<br>Charles Weibel

We show that the category HI of homotopy invariant Nisnevich sheaves with transfers and the category CycMod are each equipped with a strong filtrations and a strong cofiltration. To do so, we first define pre-coradicals and coradicals on well-powered abelian categories, and show that every isomorphism class of coradical is associated to a canonical torsion theory. We then summarize the theory of motivic cohomology needed to define $\mathbf{H I}$, its symmetric monoidal structure $\otimes^{H}$ and its partial internal hom $\underline{H o m}_{\mathbf{H I}}$. Along the way, we recall the construction of the slice filtration on $\mathbf{D M}^{\text {eff,- }}$, and extend the filtration structure on $\mathbf{D M}{ }^{\text {eff,- }}$ to $\mathbf{D M}$.

We then define and construct the torsion filtration on HI by constructing a sequence of coradicals. We explain how the torsion filtration is related to the slice filtration on $\mathbf{D M}{ }^{\text {eff,- }}$. We extend the torsion filtration to the category $\mathbf{H I}_{*}$ of homotopic modules. Appealing to the categorical equivalence between $\mathbf{H I}_{*}$ and $\mathbf{C y c M o d}$, we obtain the torsion filtration on CycMod. Finally, we generalize the conditions under which torsion filtrations exist for the heart of a tensor triangulated category.

## Acknowledgements

I would like to express gratitude to Professor Charles Weibel for his guidance, his generous support throughout the years, for the many invitations to conferences that broadened the scope of my understanding in motivic cohomology and motivic homotopy theory, for the countless hours of discussions that formed the backbone of much of this thesis, and for more countless hours spent in the editing of this thesis. Without your help, none of my thesis will be possible. Many thanks to my committee members - Professors Lev Borisov, Anders Buch, and Daniel Grayson - for the careful proofreading that ensured the accuracy and integrity of this body of work. I would also like to thank Professors Frédéric Déglise, Bruno Kahn, and Pablo Palaez for giving me various pointers that have guided me in the writing of this thesis.

I am deeply grateful to math department of Rutgers University at New Brunswick for their generous financial support, for the many help they have given me over the years, and for making my years as a graduate student a most wonderful experience. I wish to thank my parents for teaching me the strength to overcome the many challenges throughout my life. I am also fondly grateful to Denise Ichinco, who have warmed my heart with her love and encouragement. Last but not least, I would like to thank Glen Wilson, Howard Nuer, Edmund Karasiewicz, Zhuohui Zhang, Jaret Flores, Sjuvon Chung and so many other mathematicians at Rutgers - unfortunately, too many to list here - for the help, the drive, and the friendship that have taught me so much about mathematics, and above all, about being a good person.

## Dedication

To my high school math teacher, John Reutershan.

## Chapter 1

## Introduction

The goal of this thesis is to show that the abelian categories HI of homotopy invariant Nisnevich sheaves with transfers and CycMod of Rost's cycle modules admit two filtrations. Here, a (weak) filtration of a category roughly means a nested sequence of subcategories together with reflection or coreflection functors from the category to each of its subcategories. The filtrations are induced by the slice filtration on the tensor triangulated category $\mathbf{D M}{ }^{\text {eff,- }}$ of Voevodsky's derived category of motive. One of the key ingredients in constructing the three filtrations is a sequence of adjoint functors from HI to itself, coming from the triangulated tensor structure of $\mathbf{D M}{ }^{\text {eff,-- }}$. The other key ingredient is torsion theory.

We first revisit the basic definition and results of classical torsion theory for wellpowered abelian categories, as developed in [BJV] or [Dic66] (Chapter 2). However, instead of focusing on the relationship between torsion theories and radicals, we introduce the theory from the perspective of coradicals, which are radicals in the opposite category.

We then summarize the theory in motivic cohomology needed to understand the tensor triangulated structure on $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ (Chapters 3 and 4). These are taken from early lectures in [MVW]. The main results that we highlight in these two chapters are the Cancellation Theorem of Voevodsky and the existence of an object $\mathbb{Z}(1)$ of $\mathbf{D M}^{\text {eff,- }}$ which gives rise to a pair of adjoint endofunctors on $\mathbf{D M}{ }^{\text {eff,-- }}$.

These results provide the necessary scaffold to introduce the slice filtration on $\mathbf{D M}{ }^{\text {eff,- }}$. The term "slice filtration" is the name of a filtration structure on the stable homotopy category of motives that Voevodsky defined in [Voe02b]. The analogous structure for $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ is constructed by Huber and Kahn in [HK06]. We summarize
the main properties of the slice filtration on $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$ in Chapter 5, and develop an extension of the slice filtration to the category $\mathbf{D M}$, which is the triangulated category obtained from $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ by inverting the Tate motive (see Section 5.3).

In Chapter 6, we develop several filtrations on HI. We first note that $\mathbf{D M}^{\text {eff,- }}$ is equipped with a $t$-structure in the sense of [BBD], and that $\mathbf{H I}$ is categorically equivalent to the heart. An obvious question to ask is whether the filtration structure on $\mathbf{D M}{ }^{\text {eff,- }}$ induces a similar structure on $\mathbf{H I}$. In fact, the slice filtration on $\mathbf{D M}{ }^{\text {efff,- }}$ does induce two filtrations on HI. In addition, the reflection functors from one of the filtrations define a sequence of coradicals. Applying the results of Chapter 2, we obtain a third filtration, which has the additional property that the filtration on HI induces a functorial filtration of each object of HI. We coin the term "torsion filtration" to describe the filtrations that come from a sequence of coradicals.

We then extend the torsion filtrations on $\mathbf{H I}$ to the abelian category $\mathbf{H I}_{*}$ of homotopy modules (Chapter 7). The key is to construct a $\mathbb{Z}$-indexed sequence of coradicals on $\mathbf{H I}_{*}$. Once we have accomplished this, applying the results of Chapter 2, we obtain filtrations of $\mathbf{H I}_{*}$. Using the fact that $\mathbf{H I}_{*}$ is categorically equivalent to $\mathbf{C y c M o d}$, we conclude that these filtrations exist on CycMod.

In the last chapter, we summarize the results of the previous chapters by axiomatizing the conditions on a triangulated category with a $t$-structure such that the heart is equipped with a sequence of coradicals whose associated torsion theories form two filtrations on the category. The essential ingredient is for a tensor triangulated category with a $t$-structure to be equipped with a Tate object - an object $S$ in the heart such that the functor given by tensoring with $S$ admits a right adjoint - such that the Cancellation Theorem holds for $S$. We call such a triangulated category torsion monoidal, and we show that the heart of any torsion monoidal category is equipped with three filtrations, two of which are induced by a sequence of coradicals.

For the remainder of the thesis, we assume that $k$ is a perfect field.

## Chapter 2

## Coradicals and Torsion Theory

In this chapter, we develop the basics of torsion theory in a categorical setting. The concepts and results here closely follow those of [BJV] and [Dic66], except we develop the theory from the dual perspective of coradicals. The ideas are not new; neither is the methodology. We have included proofs of all results in this chapter for the convenience of the reader.

### 2.1 Coradicals

For the remainder of the chapter, let $\mathscr{A}$ be a cocomplete well-powered abelian category. That is, $\mathscr{A}$ is closed under small direct sums, and for every object $A$ in $\mathscr{A}$, the collection of subobjects of $A$ forms a set.

Definition 2.1.1. For a given subcategory $\mathscr{C}$ of an abelian category $\mathscr{A}$, and an object $A$ in $\mathscr{A}$, we say $A_{\mathscr{C}}$ is a largest $\mathscr{C}$-subobject of $A$ if $A_{\mathscr{C}}$ is a subobject of $A$ belonging to $\mathscr{C}$ such that for all subobjects $B$ in $\mathscr{C}$, the monomorphism $B \longleftrightarrow A$ factors through $A_{\mathscr{C}}$. That is, for every diagram

where $B$ is in $\mathscr{C}$, there exists a $\operatorname{map} B \xrightarrow{f} A_{\mathscr{C}}$ such that $j f=i$.
We say a subcategory $\mathscr{C}$ of $\mathscr{A}$ is reflective (resp., coreflective) if the inclusion of $\mathscr{C}$ into $\mathscr{A}$ admits a left (resp., right) adjoint $\varphi$, which we call the reflection (resp., coreflection).

If every $A$ in $\mathscr{A}$ has a largest $\mathscr{C}$ subobject, the choice of $A_{\mathscr{C}}$ for each $A$ determines a right adjoint to the inclusion of $\mathscr{C}$ in $\mathscr{A}$, making $\mathscr{C}$ a coreflective subcategory of $\mathscr{A}$.

The assumption that $\mathscr{A}$ is cocomplete and well-powered will be crucial for the following result.

Proposition 2.1.2. For a cocomplete well-powered abelian category $\mathscr{A}$ and any full subcategory $\mathscr{C}$ of $\mathscr{A}$, closed under sums and quotients in $\mathscr{A}$, any $A$ in $\mathscr{A}$ has a largest $\mathscr{C}$-subobject.

Proof. Let $A$ be an object of $\mathscr{A}$, and let $\left\{C_{i}\right\}$ be the set of subobjects of $A$ in $\mathscr{C}$. Write $A_{\mathscr{C}}$ for the image of $\oplus_{i} C_{i}$ in $A$. Since $\mathscr{C}$ is closed under sums and quotients, $A_{\mathscr{C}}$ is the desired maximal subobject of $A$ in $\mathscr{C}$.

We now define some key notions in torsion theory.

Definition 2.1.3. 1. A quotient functor is an endofunctor $\varphi: \mathscr{A} \longrightarrow \mathscr{A}$ together with a natural epimorphism $\eta:$ id $\longrightarrow \varphi$. That is, for every $f: A \longrightarrow B$, the following diagram commutes.

We will often drop the reference to $\eta$.
2. We say that $\varphi$ is idempotent if the natural epimorphism is the identity on the essential image of $\varphi$. That is, $\eta_{\varphi(A)}: \varphi(A) \longrightarrow \varphi^{2}(A)$ is a natural isomorphism.
3. A quotient functor $\varphi$ is a pre-coradical if for all $A$ in $\mathscr{A}, \varphi$ applied to the kernel of the epimorphism $A \longrightarrow \varphi(A)$ is 0 .
4. Finally, a pre-coradical $\varphi$ is a coradical if $\varphi$ is right exact.

Remark 2.1.4. Notice that quotient functors always take epimorphisms to epimorphisms. However, pre-coradicals are not always right exact. If $0 \longrightarrow A^{\prime} \longrightarrow A \longrightarrow$ $A^{\prime \prime} \longrightarrow 0$ is an exact sequence, and $\varphi$ is a pre-coradical, exactness can fail at $\varphi(A)$.

Definition 2.1.5. Let $\varphi: \mathscr{A} \longrightarrow \mathscr{A}$ be an endofunctor of an abelian category $\mathscr{C}$. We say that $\varphi$ is a pre-radical if there exists a natural monomorphism $\varphi \longrightarrow \mathrm{id}$ (in which case, we say that $\varphi$ is a subobject functor) such that $\varphi(A / \varphi(A))=0$ for all $A$. If $\varphi$ is also left-exact, then $\varphi$ is a radical.

Example 2.1.6. Let $\mathbf{A b}$ be the category of abelian groups, and let $G$ an abelian group, written additively. We write $G_{\text {tor }}$ for the torsion subgroup of $G$, and we write $\varphi(G)$ for $G / G_{t o r}$. The quotient functor $\varphi$ is a pre-coradical, but is not a coradical. To see this, consider the following short exact sequence

$$
0 \longrightarrow \mathbb{Z} \xrightarrow{2} \mathbb{Z} \longrightarrow \mathbb{Z} / 2 \longrightarrow 0
$$

in the category of $\mathbf{A b}$. Applying $\varphi$, we have

$$
0 \longrightarrow \mathbb{Z} \xrightarrow{2} \mathbb{Z} \longrightarrow 0 \longrightarrow 0
$$

which is not exact in the middle. On the other hand, it is easy to see that the functor $G \mapsto G_{t o r}$ is a radical.

More generally, let $R$ be a commutative ring, and $S$ be a multiplicatively closed set. For an $R$ module $M$, let ${ }_{S} M$ be the submodule $M$ of elements annihilated by $S$. We write $\varphi(M)$ for $M /{ }_{S} M$. Then $\varphi$ defines a pre-coradical on the category of $R$-modules. As in the case for abelian groups, the functor $\varphi$ is not a coradical.

Torsion theory is usually developed for radicals, which are coradicals in the opposite category of $\mathscr{A}$. However, throughout this chapter, we mostly consider statements for (pre-)coradicals. We leave the dual statements to the reader to formulate or look up in [Dic66] or [BJV, Section 1.2].

Proposition 2.1.7. Any right exact quotient functor $\varphi$ of an abelian category $\mathscr{A}$ is idempotent. In particular, any coradical is idempotent (cf. [BJV, I2.2]).

Proof. Fix $A$ in $\mathscr{A}$, and let $\eta$ denote the natural epimorphism associated to the quotient functor $\varphi$. Let $K$ be the kernel of $\eta_{A}: A \longrightarrow \varphi(A)$, and consider the sequence

$$
0 \longrightarrow K \longrightarrow A \longrightarrow \varphi(A) \longrightarrow 0
$$

Applying $\varphi$, which is right exact, we have

$$
\varphi(K) \longrightarrow \varphi(A) \longrightarrow \varphi^{2}(A) \longrightarrow 0
$$

Thus, $\varphi^{2}(A)$ is the cokernel of $\varphi(K) \longrightarrow \varphi(A)$. Moreover, we have the following commutative diagram:

and, since $K \longrightarrow \varphi(K)$ is an epimorphism,

$$
\begin{aligned}
\varphi^{2}(A) & =\operatorname{cok}(\varphi(K) \longrightarrow \varphi(A)) \\
& =\operatorname{cok}(K \longrightarrow \varphi(K) \longrightarrow \varphi(A)) \\
& =\operatorname{cok}(K \longrightarrow A \longrightarrow \varphi(A))
\end{aligned}
$$

But $K \longrightarrow A \longrightarrow \varphi(A)$ is the 0 map. Therefore, $\varphi^{2}(A)=\varphi(A)$ as desired.

In addition to being dual notions, there is a one-to-one correspondence between idempotent pre-radicals and idempotent pre-coradicals:

Proposition 2.1.8. Let $\varphi$ be an idempotent pre-coradical of an abelian category $\mathscr{A}$, and $\eta$ be its corresponding natural epimorphism. Write $\kappa(A)$ for $\operatorname{ker}\left(A \xrightarrow{\eta_{A}} \varphi(A)\right)$. Then $\kappa$ is a pre-radical.

Dually, if $\psi$ is an idempotent pre-radical with natural injection $\epsilon$. Writing $\gamma(A)=$ $\operatorname{cok} \epsilon_{A}$, we have that $\gamma$ is a pre-coradical.

Proof. It suffices to prove this statement for the idempotent pre-coradicals, as the statement for pre-radical is the dual assertion. We proceed as follows:

The fact that $\kappa$ is functorial follows from the naturality of $\eta$. Moreover, it is clear that $\kappa$ is a subobject functor. To see that $\kappa$ is also a pre-radical, we need to show that $\kappa(A / \kappa(A))=0$ for all $A$ in $\mathscr{A}$. Fix such an $A$, and notice that $A / \kappa(A)=\varphi(A)$. Then we have the associated short exact sequence:

$$
0 \longrightarrow \kappa(\varphi(A)) \longrightarrow \varphi(A) \longrightarrow \varphi^{2}(A) \longrightarrow 0
$$

But $\varphi(A) \longrightarrow \varphi^{2}(A)$ is the identity. It follows that $\kappa(\varphi(A))=\kappa(A / \kappa(A))=0$.
Next, consider the following short exact sequence associated to $\kappa(A)$ :

$$
0 \longrightarrow \kappa(\kappa(A)) \longrightarrow \kappa(A) \xrightarrow{\eta_{\kappa(A)}} \varphi(\kappa(A)) \longrightarrow 0 .
$$

Since $\varphi$ is a pre-coradical, we have we have that

$$
\varphi(\kappa(A))=\varphi(\operatorname{ker}(A \longrightarrow \varphi(A)))=0 .
$$

It follows that $\kappa^{2}(A)=\kappa(A)$, and $\kappa$ is idempotent. The proposition follows.

Proposition 2.1.9. Let $\varphi$ be a pre-coradical of an abelian category $\mathscr{A}$. Suppose $B$ is a quotient of $\varphi(A)$, and let $K$ be the kernel of the composition $A \longrightarrow \varphi(A) \longrightarrow B$. Then $\varphi(K)$ is isomorphic to the kernel of the epimorphism $\varphi(A) \longrightarrow B$ (cf. [BJV, I2.3]).

Proof. Let $\eta$ denote the natural epimorphism associated to the quotient functor $\varphi$, and let $f$ denote the epimorphism given by the composition $A \longrightarrow \varphi(A) \longrightarrow B$.

Consider the exact sequence $0 \longrightarrow K \longrightarrow A \longrightarrow B \longrightarrow 0$. We claim that $\varphi(K) \longrightarrow$ $\varphi(A) \longrightarrow B \longrightarrow 0$ is exact and fits into the following commutative diagram:

Notice that $\eta_{K}: K \longrightarrow \varphi(K)$ is epi. Therefore, the cokernel of $\varphi(g)$ is the cokernel of $K \longrightarrow A \longrightarrow \varphi(A)$. But the epimorphism $A \longrightarrow B$ factors through $\varphi(A)$. It follows that $\operatorname{cok} \varphi(g)=B$. The rest of the claim now follows.

Let $L$ be the kernel of $\eta_{A}$. We claim that $L$ is also the kernel of the $\eta_{K}$. Since $f$ factors through $A \longrightarrow \varphi(A)$, there exists a map from $L$ to $K$, which we call $h$. Applying the Snake Lemma to the following commutative diagram:

we have that $L$ is a subobject of $K$. Let $L^{\prime}$ be the kernel of $K \longrightarrow \varphi(K)$. We claim that $L$ is isomorphic to $L^{\prime}$. Notice that we have the following commutative diagram:

Since $\eta_{A} \circ g \circ i^{\prime}=\varphi(g) \circ \eta_{K} \circ i^{\prime}=0$, there exists a map $j$ from $L^{\prime}$ to $L$ (dotted arrow in (2.1.10)) such that $i j=g i^{\prime}$. Applying the Snake Lemma to (2.1.10), we see that $j$ is injective.

By the naturality of $\eta$, we also have the following commutative square:

Since $\varphi$ is a pre-coradical, $\varphi(L)=0$. Therefore, $\eta_{K} \circ h=0$. Thus, there exists a map $j^{\prime}: L \longrightarrow L^{\prime}$ such that $j \circ j^{\prime}=\operatorname{id}_{L}$ and $j^{\prime} \circ j=\operatorname{id}_{L^{\prime}}$. It follows that $L \cong L^{\prime}$. Applying the Snake Lemma to (2.1.10), we see that $\varphi(K) \longrightarrow \varphi(A)$ is injective, as desired.

### 2.2 Torsion theories and coradicals

Definition 2.2.1. A torsion theory for an abelian category $\mathscr{A}$ is a pair $(\mathscr{T}, \mathscr{F})$ of full subcategories, called the torsion subcategory and the torsion-free subcategory respectively, where the objects of $\mathscr{T}$ are the objects $T$ such that $\operatorname{Hom}_{\mathscr{A}}(T, F)=0$ for every $F$ in $\mathscr{F}$ and the objects of $\mathscr{F}$ are the objects $F$ such that $\operatorname{Hom}_{\mathscr{A}}(T, F)=0$ for every object $T$ in $\mathscr{T}$.

Certainly $0 \in \mathscr{T} \cap \mathscr{F}$. Therefore, neither subcategory is empty. We also have the following characterization of the torsion and torsionfree subcategories.

Proposition 2.2.2. Suppose $\mathscr{T}$ and $\mathscr{F}$ are two full subcategories of a cocomplete wellpowered abelian category $\mathscr{A}$. Then $\mathscr{T}$ is the torsion subcategory of a torsion theory of $\mathscr{A}$ if and only if $\mathscr{T}$ is closed under extensions, direct sums and quotients.

Dually, $\mathscr{F}$ is a torsionfree subcategory of a torsion theory of $\mathscr{A}$ if and only if $\mathscr{F}$ is closed under extensions, direct products, and subobjects. (cf. [BJV, I2.6])

Proof. It suffices to verify the statement for torsion subcategories. Suppose $\mathscr{T}$ is a torsion subcategory with $\mathscr{F}^{\prime}$ its corresponding torsionfree subcategory.

Closed under quotients: suppose $T$ is an object of $\mathscr{T}$. For any epimorphism $T \longrightarrow T^{\prime}$, we have

$$
0 \longrightarrow \operatorname{Hom}_{\mathscr{A}}\left(T^{\prime}, F\right) \longrightarrow \operatorname{Hom}_{\mathscr{A}}(T, F)
$$

for any $F$ in $\mathscr{F}^{\prime}$. However, $\operatorname{Hom}_{\mathscr{A}}(T, F)=0$. Therefore, $\operatorname{Hom}_{\mathscr{A}}\left(T^{\prime}, F\right)=0$ for all $F$, and $Y$ is in $\mathscr{T}$.

Closed under sums: suppose $\left\{T_{i}\right\}_{i \in I}$ is a collection of objects of $\mathscr{T}$. We have

$$
\operatorname{Hom}_{\mathscr{A}}\left(\oplus_{i \in I} T_{i}, F\right)=\prod_{i \in I} \operatorname{Hom}_{\mathscr{A}}\left(T_{i}, F\right)=0
$$

for all $F$ in $\mathscr{F}^{\prime}$. It follows that $\oplus_{i \in I} T_{i}$ is an object of $\mathscr{T}$.

Closed under extensions: Suppose

$$
0 \longrightarrow T^{\prime} \longrightarrow A \longrightarrow T^{\prime \prime} \longrightarrow 0
$$

is an exact sequence in $\mathscr{A}$ with $T^{\prime}, T^{\prime \prime} \in \mathscr{T}$. Then for any $F$ in $\mathscr{F}$,

$$
0 \longrightarrow \operatorname{Hom}_{\mathscr{A}}\left(T^{\prime \prime}, F\right) \longrightarrow \operatorname{Hom}_{\mathscr{A}}(A, F) \longrightarrow \operatorname{Hom}_{\mathscr{A}}\left(T^{\prime}, F\right) .
$$

Since $\operatorname{Hom}_{\mathscr{A}}\left(T^{\prime \prime}, F\right)=\operatorname{Hom}_{\mathscr{A}}\left(T^{\prime}, F\right)=0$, it follows that $\operatorname{Hom}_{\mathscr{A}}(A, F)=0$ for all $F$. Therefore, $A$ is in $\mathscr{T}$.

Conversely, suppose $\mathscr{T}$ is closed under extensions, direct sums and quotients. Let $\mathscr{F}^{\prime}$ be the full subcategory of $F$ such that $\operatorname{Hom}_{\mathscr{A}}(T, F)=0$ for all $T$ in $\mathscr{T}$, and let $\mathscr{T}^{\prime}$ be the full subcategory of $\mathscr{A}$ whose objects are all $T^{\prime}$ such that $\operatorname{Hom}_{\mathscr{A}}\left(T^{\prime}, F\right)=0$ for all $F$ in $\mathscr{F}$. We claim that $\mathscr{T}^{\prime}=\mathscr{T}$.

Clearly, $\mathscr{T}$ is a full subcategory of $\mathscr{T}^{\prime}$. Let $T$ be an object of $\mathscr{T}^{\prime}$. By Proposition 2.1.2, there exists a maximal $\mathscr{T}$-subobject of $T$, which we represent by $T_{\mathscr{T}}$. We show that $T / T_{\mathscr{T}}$ is an object of $\mathscr{F}^{\prime}$, and therefore it must be 0 .

Suppose not. Then there exists some $T^{\prime}$ in $\mathscr{T}$ with a nonzero map $f: T^{\prime} \longrightarrow T / T_{\mathscr{T}}$. Since $f\left(T^{\prime}\right)$ is an object in $\mathscr{T}$, replacing $T^{\prime}$ by its image in $T / T_{\mathscr{T}}$, we may assume without loss of generality that $f$ is monic.

Pull back $T \longrightarrow T / T_{\mathscr{T}}$ by $f$, and we have:

As $i$ is a pullback of a monomorphism, $i$ is itself monic. As $T \longrightarrow T / T_{\mathscr{T}}$ is epimorphic, so is $p$. Furthermore, ker $p=T_{\mathscr{T}}$. Since $T_{\mathscr{T}}$ and $T^{\prime}$ are both in $\mathscr{T}$, it follows that $P$ must be in $\mathscr{T}$ as well. However, $T^{\prime}$ is nontrivial, contradicting the maximality of $T_{\mathscr{T}}$. Thus, $T / T_{\mathscr{T}} \in \mathscr{F}$, and $T \in \mathscr{T}$.

Proposition 2.2.3. Let $(\mathscr{T}, \mathscr{F})$ be a pair of full subcategories of a cocomplete wellpowered abelian category $\mathscr{A}$. Then $(\mathscr{T}, \mathscr{F})$ is a torsion theory if and only if the following conditions hold:

1. the only common object of $\mathscr{T}$ and $\mathscr{F}$ is 0 .
2. for every $A$ in $\mathscr{A}$, there exists a subobject $A_{\mathscr{T}}$ of $A$ in $\mathscr{T}$ such that $A / A_{\mathscr{T}}$ is an object of $\mathscr{F}$.
(cf. [BJV, I2.7])
Proof. $\Rightarrow$ : Suppose $A$ is $\mathscr{T} \cap \mathscr{F}$. Then $\operatorname{Hom}_{\mathscr{A}( }(A, A)=0$, so the identity is the zero map, and $A=0$. Now, for $A$ in $\mathscr{A}$, let $A_{\mathscr{T}}$ be its maximal $\mathscr{T}$ subobject. By the same reasoning as in the previous proposition, $A / A_{\mathscr{T}}$ is an object of $\mathscr{F}$.
$\Leftarrow$ : suppose $\mathscr{T}, \mathscr{F}$ satisfy the condition of the proposition, and there is some $A$ in $\mathscr{A}$ such that for all $F$ in $\mathscr{F}, \operatorname{Hom}_{\mathscr{A}}(A, F)=0$. Let $A_{\mathscr{T}}$ denote the $\mathscr{T}$-subobject in Condition (2) associated to $A$. Since $A / A_{\mathscr{T}} \in \mathscr{F}, A \longrightarrow A / A_{\mathscr{T}}$ is the zero map. Hence, $A=A_{\mathscr{T}}$, and $A$ is in $\mathscr{T}$. Similarly, if $F \in \mathscr{F}$, then the inclusion $F_{\mathscr{T}} \longrightarrow F$ is the zero map, and hence $F / F_{\mathscr{T}}=F$ which is in $\mathscr{F}$.

Proposition 2.2.4. Let $(\mathscr{T}, \mathscr{F})$ be a torsion theory for a cocomplete well-powered abelian category $\mathscr{A}$. Sending $A$ in $\mathscr{A}$ to its largest $\mathscr{T}$-subobject $A_{\mathscr{T}}$ defines an idempotent pre-radical.

Dually, sending $A$ to $A / A_{\mathscr{T}}$ defines an idempotent pre-coradical (cf. [BJV, I2.8]).

Proof. In this case, it is easier to prove the statement for idempotent pre-radicals. Let $\kappa$ denote the association defined by $A \mapsto A_{\mathscr{A}}$ for $A$ in $\mathscr{A}$.

To see that $\kappa$ is a functor, let $f: A \longrightarrow B$ be any morphism. The image of $\kappa(A)$ in $B$ under $f$ is in $\mathscr{T}$. By the maximality of $\kappa(B)$, there exists a map $g: f(\kappa(A)) \longrightarrow \kappa(B)$, and define the map $\kappa(f)$ to be the composition of $\left.g f\right|_{\kappa(A)}$.

It is clear from the construction that $\kappa$ is a subobject functor. Since $\kappa(A) \in \mathscr{T}$, it is clear that the largest suboboject of $\kappa(A)$ is itself: hence $\left.\varphi^{2}(A)\right)=\varphi(A)$. By the maximality of $\kappa(A), A / \kappa(A) \in \mathscr{F}$, and

$$
\kappa(A / \kappa(A))=0 .
$$

The dual statement follows from Proposition 2.1.8.

Remark 2.2.5. Since a coradical $\varphi$ is left adjoint to the inclusion of its associated torsionfree subcategory $\mathscr{F}$ in $\mathscr{A}$ and its associated idempotent pre-radical $\kappa$ is right adjoint to the inclusion of the torsion subcategory $\mathscr{T}$ in $\mathscr{A}, \mathscr{T}$ is a coreflective subcategory, and $\mathscr{F}$ is a reflective subcategory of $\mathscr{A}$.

Theorem 2.2.6. Let $\mathscr{A}$ be a cocomplete well-powered abelian category. There is a one-to-one correspondence between isomorphism classes of idempotent pre-coradicals of $\mathscr{A}$ and torsion theories for $\mathscr{A}$. If $\varphi$ is a pre-coradical, and $\eta$ is its associated natural epimorphism, then the torsion theories are defined by

$$
\begin{aligned}
\mathscr{T} & =\{T \mid \varphi(T)=0\} \\
\mathscr{F} & =\left\{F \mid \eta_{F}: F \longrightarrow \varphi(F) \text { is an isomorphism }\right\} .
\end{aligned}
$$

(cf. [BJV, I2.9]).

Proof. Obtaining an idempotent pre-coradical from a torsion theory is established by Proposition 2.2.4. Therefore, it suffices to show that $(\mathscr{T}, \mathscr{F})$ as given in the statement of the theorem defines a torsion theory on $\mathscr{A}$, and that the associations define quasiinverses of one another.

To do this, we appeal to Proposition 2.2.3. It is clear that the only object common to both $\mathscr{T}$ and $\mathscr{F}$ is 0 . So we need only to show that for every $A$ in $\mathscr{A}$, there exists $T$ in $\mathscr{T}$ such that $A / T \in \mathscr{F}$.

Fix $A$ in $\mathscr{A}$. Since $\varphi$ is idempotent, $\varphi(A)$ is in $\mathscr{F}$. Since $\varphi$ is a pre-coradical, the kernel of $A \longrightarrow \varphi(A)$ is in $\mathscr{T}$.

As we have mentioned in the paragraph preceding Proposition 2.1.7, there is a result corresponding to Theorem 2.2.6 for radicals: the isomorphism classes of idempotent pre-radical $\kappa$ are in one-to-one correspondence with torsion theories on $\mathscr{A}$. For a given pre-radical $\kappa$ with natural inclusion $\epsilon$, the associated torsion theory is defined by

$$
\begin{aligned}
& \mathscr{T}=\left\{T \mid \epsilon_{F}: \kappa(T) \longrightarrow T \text { is an isomorphism }\right\} \\
& \mathscr{F}=\{F \mid \kappa(F)=0\} .
\end{aligned}
$$

In fact, we have the following.

Corollary 2.2.7. Let $\varphi$ be an idempotent pre-coradical, and let $\kappa$ be the idempotent pre-radical associated to $\varphi$ (see Proposition 2.1.8). Then the torsion theory defined by $\varphi$ in Theorem 2.2.6 is the same as the one for $\kappa$ as defined above.

Moreover, $\varphi$ is left adjoint to the inclusion $\mathscr{F} \longrightarrow \mathscr{A}$ and $\kappa$ is right adjoint to the inclusion $\mathscr{T} \longrightarrow \mathscr{A}$.

Proof. The only thing left to verify is that $\varphi$ defines a left adjoint to the inclusion of $\mathscr{F}$ into $\mathscr{A}$ and $\kappa$ defines a right adjoint to the inclusion of $\mathscr{T}$ into $\mathscr{A}$. We verify the statement only for $\varphi$ and leave the latter to the reader.

For $\varphi$, let $A$ be an object of $\mathscr{A}$, and let $F$ be an object of $\mathscr{F}$. Consider the short exact sequence

$$
0 \longrightarrow \kappa(A) \longrightarrow A \longrightarrow \varphi(A) \longrightarrow 0
$$

Applying $\operatorname{Hom}_{\mathscr{A}}(-, F)$, we have the exact sequence

$$
0 \longrightarrow \operatorname{Hom}_{\mathscr{A}}(\varphi(A), F) \longrightarrow \operatorname{Hom}_{\mathscr{A}}(A, F) \longrightarrow \operatorname{Hom}_{\mathscr{A}}(\kappa(A), F)
$$

Since $\kappa(A) \in \mathscr{T}($ Theorem 2.2.6 $)$ and $\varphi(A) \in \mathscr{F}, \operatorname{Hom}_{\mathscr{A}}(\kappa(A), F)=0$, and

$$
\operatorname{Hom}_{\mathscr{A}}(\varphi(A), F)=\operatorname{Hom}_{\mathscr{F}}(\varphi(A), F) \cong \operatorname{Hom}_{\mathscr{A}}(A, F)
$$

as desired.

It should be evident from Theorem 2.2.6 that isomorphism classes of coradicals are not in one-to-one correspondence with torsion theories, although they do give rise to unique torsion theories. We now characterize the properties of the torsion theories that arise from coradicals.

Definition 2.2.8. Let $(\mathscr{T}, \mathscr{F})$ be a torsion theory on $\mathscr{A}$. We say that $(\mathscr{T}, \mathscr{F})$ is hereditary if $\mathscr{T}$ is closed with respect to subobjects. That is, if $A \hookrightarrow B$ is an monomorphism in $\mathscr{A}$ such that $B \in \mathscr{T}$, then $A \in \mathscr{T}$.

Dually, we say that $(\mathscr{T}, \mathscr{F})$ is cohereditary if $\mathscr{F}$ is closed under quotients.
Theorem 2.2.9. Let $\mathscr{A}$ be a cocomplete well-powered abelian category. There is a one-to-one correspondence between isomorphism classes of coradicals of $\mathscr{A}$ and cohereditary torsion theories on $\mathscr{A}$ (cf. [BJV, I2.12]).

Proof. From coradicals to cohereditary torsion theories: Let $\varphi$ be a coradical with natural epimorphisms $\eta$, and ( $\mathscr{T}, \mathscr{F}$ ) the associated torsion theory, given by Theorem 2.2.6.

We need only to show that $\mathscr{F}$ defined by $\{A \mid \eta: A \longrightarrow \varphi(A)$ is an isomorphism $\}$ is closed under quotients. Let $f: F \longrightarrow A$ be an epimorphism with $F$ in $\mathscr{F}$, and write $K$ for the kernel of $f$. It follows from Proposition 2.2.2 that $\mathscr{F}$ is closed under subobjects. Hence, $K \in \mathscr{F}$. Furthermore, by the right exactness of $\varphi$, we have

whence $A=\varphi(A)$ as desired. It follows that $A \in \mathscr{F}$.

From cohereditary torsion theory to coradicals: Let $(\mathscr{T}, \mathscr{F})$ be a cohereditary torsion theory on $\mathscr{A}$, and let $\varphi$ be its associated idempotent pre-coradical given by Theorem 2.2.6. We need to show that $\varphi$ is right exact.

We begin by demonstrating that, for an epimorphism $f: A \longrightarrow B$ in $\mathscr{A}, \varphi(B)$ is isomorphic to the push-out $P$ of $f$ and the natural epimorphism $\eta_{A}: A \longrightarrow \varphi(A)$, as
in the following diagram:

Since $\varphi$ is left adjoint to inclusion, we have that

$$
\operatorname{Hom}_{\mathscr{A}}(\varphi(B), F)=\operatorname{Hom}_{\mathscr{F}}(\varphi(B), F)=\operatorname{Hom}_{\mathscr{A}}(B, F)
$$

for all $F$ in $\mathscr{F}$. In particular, for all $F$ in $\mathscr{F}$, and epimorphisms $B \longrightarrow F$, there exists a unique map $\varphi(B) \longrightarrow F$ making the following diagram commutative

Now, since $P$ is the push-out, and $\varphi(B)$ fits into the following commutative diagram

there exists an unique map $P \longrightarrow \varphi(B)$. Furthermore, the map $\varphi(A) \longrightarrow P$ is an epimorphism since it is the push-out of the epimorphism $A \longrightarrow B$. Since $\varphi(A) \in \mathscr{F}$, which is closed under quotients, it follows that $P \in \mathscr{F}$. The map $B \longrightarrow P$ is also an epimorphism because it is the push-out of the epimorphism $A \longrightarrow \varphi(A)$. It follows by the previous point that there exists an unique map $\varphi(B) \longrightarrow P$.

Since both maps are unique, it follows that each map is an isomorphism and is the inverse of the other. Furthermore, Diagram (2.2.10) is a push-out diagram.

To complete the proof that $\varphi$ is right exact, we need only to show that for an exact sequence

$$
0 \longrightarrow A^{\prime} \xrightarrow{f} A \xrightarrow{g} A^{\prime \prime} \longrightarrow 0
$$

in $\mathscr{A}, \varphi\left(A^{\prime \prime}\right)$ is the cokernel of $\varphi\left(A^{\prime}\right) \longrightarrow \varphi(A)$. Consider the commutative diagram

where the top row is exact. Since the composition $\varphi\left(A^{\prime}\right) \longrightarrow \varphi(A) \longrightarrow \varphi\left(A^{\prime \prime}\right)$ is 0 , there exists an unique map $\operatorname{cok} \varphi(f) \xrightarrow{p} \varphi\left(A^{\prime \prime}\right)$ (shown as the dotted arrow in the diagram above), such that $p h=\varphi(g)$.

However, we also have that $h \circ \eta_{A} \circ f=h \circ \varphi(f) \circ \eta_{A^{\prime}}=0$. It follows that there exists a map $A^{\prime \prime} \longrightarrow \operatorname{cok} \varphi(f)$ (represented by the dotted arrow in the following diagram) such that the following diagram is commutative:

But $\varphi\left(A^{\prime \prime}\right)$, as a push-out, admits an unique map $\varphi\left(A^{\prime \prime}\right) \xrightarrow{p^{\prime}} \operatorname{cok} \varphi(f)$. Once again, since the maps defined between $\varphi\left(A^{\prime \prime}\right)$ and $\operatorname{cok} \varphi(f)$ are unique with respect to $\varphi(g)$ and $h$, it follows that $p$ and $p^{\prime}$ are isomorphisms and define inverses of one another. This concludes the theorem.

Remark 2.2.11. Notice that if $\varphi$ is a coradical, then $\mathscr{F}$ is a Serre subcategory of $\mathscr{A}$. In particular, $\mathscr{F}$ is an abelian category. In the case when $\mathscr{A}$ has "enough $\mathscr{F}$-covers", then the torsion subcategory $\mathscr{T}$ is precisely the localization of $\mathscr{A}$ by $\mathscr{F}$ in the sense of [Swan], and the associated idempotent radical $\kappa$ is an exact radical.

## Chapter 3

## Homotopy Invariant Sheaves with Transfers

In this chapter, we define the notion of homotopy invariant Nisnevich sheaves with transfers. In order to do so, we need to introduce the category of correspondences and presheaves with transfers.

For the remainder of the thesis, let $k$ be a perfect field, and let $\mathrm{Sm}_{k}$ denote the category of smooth separated finite type $k$-schemes. The material in this chapter is taken from Lecture 2 and 6 of [MVW].

### 3.1 Sheaves with Transfers

Definition 3.1.1. Let $X, Y$ be smooth separated $k$-schemes. An elementary correspondence from $X$ to $Y$ is an irreducible closed subset $W$ of $X \times Y$ such that the projection to $X$ from the associated integral subscheme $\bar{W}$ is finite and surjective onto a component of $X$.

Let $\operatorname{Cor}_{k}(X, Y)$ (or simply $\operatorname{Cor}(X, Y)$ in the case when the base field $k$ is understood) denote the free abelian group generated by the elementary correspondences from $X$ to $Y$. Elements of $\operatorname{Cor}(X, Y)$ are called finite correspondences from $X$ to $Y$.

Example 3.1.2. In the case when $X$ is an integral scheme over $k$, the graph of any morphism $\varphi: X \longrightarrow Y$ defines an elementary correspondence from $X$ to $Y$.

In the case where $X=Y=\operatorname{Spec} L$, where $L / k$ is a Galois extension, the elementary correspondences are precisely the graphs of the automorphisms in the Galois group $G \stackrel{\text { def }}{=} \operatorname{Gal}(L, k)$. In this case, $\operatorname{Cor}_{k}(X, Y)=\mathbb{Z}[G]$.

Let $C o r_{k}$ be the collection of objects and morphisms where the objects of $C o r_{k}$ are smooth separated finite type $k$-schemes and whose morphisms from $X$ to $Y$ in $\operatorname{Cor}_{k}$
are given by $\operatorname{Cor}(X, Y)$. We claim that $C o r_{k}$ forms a category. The main missing piece here is a description of the composition of morphisms. We can define the composition of a finite correspondence $V$ in $\operatorname{Cor}(X, Y)$ with a finite correspondence $W$ in $\operatorname{Cor}(Y, Z)$ via the following construction taken from the discussion preceding [MVW, 1.5] and [MVW, 1.7]. Reduce to the case where $X$ and $Y$ are connected, and suppose that $V$ and $W$ are irreducible closed subsets of $X \times Y$ and $Y \times Z$ respectively. Let $\tilde{V}$ and $\tilde{W}$ be the underlying integral schemes associated to $V$ and $W$. Then $\tilde{V} \times X$ and $X \times \tilde{W}$ define cycles in $X \times Y \times Z$ intersecting properly in the sense of [Ful84, 2.4]. Let $T$ be the image of $\tilde{V} \times_{Y} \tilde{W}$ in $X \times Y \times Z$. Each irreducible component $T_{i}$ of $T$ is finite and surjective over $X$ by [MVW, 1.7]. Furthermore, the image of $T_{i}$ along $p: X \times Y \times Z \longrightarrow X \times Z$ is an irreducible closed subscheme of $X \times Z$ by [MVW, 1.4]. Let $[T]$ be the cycle corresponding to $T$ in $X \times Y \times Z$. The push-forward $p_{*}([T])$ defines a finite correspondence from $X$ to $Z$, which we define to be the composition $V \circ W$.

Definition 3.1.3. A presheaf with transfers is a contravariant functor from Cor $_{k}$ to abelian groups (or $R$-modules for some commutative ring $R$ ). A map between presheaves $F$ and $G$ is a natural transformation from $F$ to $G$. Let $\mathbf{P S T}_{k}$ (or simply PST in the case when there is no ambiguity about the basefield $k$ ) denote the category of presheaves with transfers. Notice that PST has a natural structure of an abelian category.

Remark 3.1.4. The term "with transfers" comes from the existence of transfer maps. For $F$ in PST, and a finite surjective morphism $\varphi: W \longrightarrow X$ of smooth schemes, there exists a map $\varphi_{*}: F(W) \longrightarrow F(X)$ induced by the graph of $\varphi$, regarded as an elementary correspondence from $W$ to $X$. We call $\varphi_{*}$ the transfer map. Notice that $\varphi_{*}$ is in the "opposite direction" as the induced maps between sections.

Definition 3.1.5. ([SGA4, II.1.3]) A Grothendieck pre-topology on a category $\mathscr{C}$ is a collection $\mathscr{U}$ of covering families indexed by the objects of $\mathscr{C}$. Here, for each $X$ in $\mathscr{C}$, a covering family of $X$ is a collection of sets of morphisms $\left\{U_{\alpha} \longrightarrow X\right\}_{\alpha}$ called covers of $X$. Together, the covering families satisfy the following axioms:

1. for every map $Y \longrightarrow X$ in $\mathscr{C}$ and every cover $\left\{U_{\alpha} \longrightarrow X\right\}$ of $X$, the pullback
$Y \times U_{\alpha} \longrightarrow Y$ exists for every $\alpha$, and $\left\{U_{\alpha} \times_{X} Y \longrightarrow Y\right\}$ is a cover of $Y$.
2. If $\left\{U_{\alpha} \longrightarrow X\right\}$ is a cover of $X$ and for each $\alpha,\left\{V_{\alpha \beta} \longrightarrow U_{\alpha}\right\}$ is a cover of $U_{\alpha}$, then $\left\{V_{\alpha \beta} \longrightarrow X\right\}$ obtained via composition is a cover of $X$.
3. If $X^{\prime} \longrightarrow X$ is an isomorphism, then $\left\{X^{\prime} \longrightarrow X\right\}$ is a cover of $X$.

Remark 3.1.6. The notion of Grothendieck pre-topology generalizes the notion of a topology on a space $X$. Specifically, regarding a topology of $X$ as a category $\mathscr{T}_{X}$ where the objects are open subsets of $X$ and the morphisms are inclusion maps, then the collections $\left\{V_{i} \subset V\right\}$ of all covers of $V$, as $V$ ranges over all open subsets of $X$ satisfy the axioms of Definition 3.1.5 and define a Grothendieck pre-topology on $\mathscr{T}_{X}$.

Definition 3.1.7. For let $S \stackrel{\text { def }}{=}\left\{\varphi_{\alpha}: U_{\alpha} \longrightarrow X\right\}$ be a collection of morphisms between schemes. We say that $S$ is jointly surjective if $\bigcup_{\varphi_{\alpha} \in S} \varphi_{\alpha}\left(U_{\alpha}\right)=X$.

Remark 3.1.8. For each $X$, consider the collection $\mathscr{U}_{X}$ of jointly surjective sets of open immersions $\left\{U_{\alpha} \longrightarrow X\right\}$. Then $\mathscr{U}_{X}$ as $X$ ranges over all finite type $k$-schemes form a Grothendieck pre-topology $\mathscr{U}$ on the category $S c h_{k}$ of finite type $k$-schemes called the large Zariski site on $k$-schemes.

We are interested in two other important Grothendieck pre-topologies on $\mathrm{Sm}_{k}$. They are the étale site and the Nisnevich site, which we define below. Recall that a morphism $\varphi: X \longrightarrow Y$ is étale if $\varphi$ is a flat and unramified. (See [Milne, §1.3].)

Definition 3.1.9. The large étale site on $\mathrm{Sm}_{k}$, is the Grothendieck pre-topology given by a jointly surjective sets of étale morphisms $\left\{U_{\alpha} \longrightarrow X\right\}$.

The large Nisnevich site on $\mathrm{Sm}_{k}$ is the Grothendieck pre-topology such that every cover of $X$ is an étale cover $\left\{U_{\alpha} \longrightarrow X\right\}$ such that for every $x$ in $X$, there exists some $\varphi_{\alpha}: U_{\alpha} \longrightarrow X$ and $y$ in $U_{\alpha}$ such that $\varphi_{\alpha}(y)=x$ and the induced map $k(x) \longrightarrow k(y)$ is an isomorphism.

Let $\mathrm{Sm}_{k, \text { ét }}$ and $\mathrm{Sm}_{k, \text { Nis }}$ denote respectively the étale and Nisnevich site of smooth schemes over $k$.

Since open immersions are étale, a jointly surjective collection of open immersions is both an étale cover and a Nisnevich cover. In this sense, the Zariski topology is coarser than the Nisnevich topology, which, in turn, is coarser than the étale topology on $\mathrm{Sm}_{k}$.

Definition 3.1.10. An étale sheaf with transfers (resp. Nisnevich sheaf with transfers) $F$ is a presheaf with transfers that is also an étale (resp. Nisnevich) sheaf. That is, $F$ satisfies the following coherence conditions:

1. for each étale (resp. Nisnevich) cover $\left\{U_{\alpha} \longrightarrow X\right\}$, the following sequence is exact:

$$
0 \longrightarrow F(X) \longrightarrow \prod_{\alpha} F\left(U_{\alpha}\right) \longrightarrow \prod_{\alpha, \beta} F\left(U_{\alpha} \times_{X} U_{\beta}\right)
$$

where the map $\prod_{\alpha} F\left(U_{\alpha}\right) \longrightarrow \prod_{\alpha, \beta} F\left(U_{\alpha} \times_{X} U_{\beta}\right)$ is given by the first and second projections from $U_{\alpha} \times{ }_{X} U_{\beta}$ to $U_{\alpha}$ and $U_{\beta}$ respectively for each $\alpha, \beta$.
2. for each $U, V, F(U \sqcup V)=F(U) \oplus F(V)$.

We write $S h_{\text {et }} C o r$ (resp. $S h_{\text {Nis }} C o r$ ) for the subcategory of étale (resp. Nisnevich) sheaves with transfers.

Since the category of sheaves on any locale is well-powered (see [Bo, 2.3.7]), the category of étale sheaves with transfers is also well-powered. So is the category of Nisnevich sheaves with transfers.

It is clear from the definition and the discussion following Definition 3.1.9 that an étale sheaf is also a Nisnevich sheaf, and an Nisnevich sheaf is a Zariski sheaf.

Our focus will be on Nisnevich sheaves with transfers, and here are some prominent examples.

Example 3.1.11. The constant sheaf $\mathbb{Z}$, the structure sheaf $\mathcal{O}$, and the sheaf of global units $\mathcal{O}^{*}$ are examples of étale and Nisnevich sheaves with transfers as defined in Definition 3.1.10. To see that $\mathbb{Z}, \mathcal{O}$, and $\mathcal{O}^{*}$ are étale and Nisnevich sheaves with transfers, we need to define the map $\varphi^{*}: \mathbb{Z}(Y) \longrightarrow \mathbb{Z}(X)$ (resp., $\mathcal{O}(Y) \longrightarrow \mathcal{O}(X), \mathcal{O}^{*}(Y) \longrightarrow \mathcal{O}^{*}(X)$ ) for every finite correspondence in $\operatorname{Cor}(X, Y)$.

Assume that $X$ and $Y$ are integral schemes in $\mathrm{Sm}_{k}$, and $W$ is an elementary correspondence from $X$ to $Y$. Then, $W$ is given by an integral scheme finite over $X$, which
we also represent by $W$. Let $F$ and $L$ be the function fields of $X$ and $W$ respectively. Then, $L$ is an $n$-dimensional $F$-vector space, for some positive integer $n$. The induced map $\mathbb{Z}(X) \longrightarrow \mathbb{Z}(Y)$ is given by

$$
\mathbb{Z}=\mathbb{Z}(Y) \xrightarrow{n} \mathbb{Z}(X)=\mathbb{Z} .
$$

For the others, let $t r: L \longrightarrow F$ and $N: L \longrightarrow F$ denote the trace and norm maps respectively. Since $X$ is normal and $W$ is finite over $X, \operatorname{tr}$ and $N$ restrict to homomorphisms $\mathcal{O}(W) \longrightarrow \mathcal{O}(X)$ and $\mathcal{O}^{*}(W) \longrightarrow \mathcal{O}^{*}(X)$ respectively. Hence, the map $\mathcal{O}(Y) \longrightarrow \mathcal{O}(X)$ is given by the composition

$$
\mathcal{O}(Y) \longrightarrow \mathcal{O}(W) \xrightarrow{t r} \mathcal{O}(X),
$$

and the map $\mathcal{O}^{*}(Y) \longrightarrow \mathcal{O}^{*}(X)$ is given by

$$
\mathcal{O}^{*}(Y) \longrightarrow \mathcal{O}^{*}(W) \xrightarrow{N} \mathcal{O}^{*}(X)
$$

Example 3.1.12. A large class of Nisnevich sheaves with transfers are the representable sheaves. For each $X$ in $\operatorname{Sm}_{k}$, write $\mathbb{Z}_{\mathrm{tr}}(X)$ for the sheaf which associates to each $U$ the abelian group $\operatorname{Cor}(U, X)$. To see that $\mathbb{Z}_{\operatorname{tr}}(X)$ is a Nisnevich sheaf, it suffices to show that it is an étale sheaf. In particular, for each $X$ in $\operatorname{Sm}_{k}, \mathbb{Z}_{\mathrm{tr}}(X)$ satisfies the coherence conditions given in Definition 3.1.10. The statement that $\mathbb{Z}_{\operatorname{tr}}(X)$ is an étale sheaf is proven in [MVW, 6.2].

Let $a_{\text {ét }}$ (resp. $a_{\text {Nis }}$ ) denote the étale (resp. Nisnevich) sheafification of a (general) presheaf on $\mathrm{Sm}_{k}$. (See [Tamme, 3.1.1].) Furthermore, for a presheaf with transfers $F$, let $F_{\text {ét }}\left(\right.$ resp. $F_{\text {Nis }}$ ) denote the étale (resp. Nisnevich) sheafification of $F$.

Proposition 3.1.13. 1. For $F$ a presheaf with transfers, $F_{\text {ét }}$ has a unique structure of presheaf with transfers, and the canonical map $F \longrightarrow($ ét $F$ ) is a morphism of presheaves with transfers.

The functor $a_{\text {ét }}$ restricted to PST defines a left adjoint to the inclusion of $S h_{\text {et }} C$ or into PST.

Likewise, for $F$ in PST, $F_{\text {Nis }}$ is a Nisnevich sheaf with transfers, and $a_{\text {Nis }} r e-$ stricted to PST defines a left adjoint to the inclusion of $S h_{\mathrm{Nis}} C$ or into PST.
2. Both $S h_{\text {ét }} C$ or and $S h_{\text {Nis }} C o r$ are abelian subcategories of PST with enough injectives.

Proof. For the statements about étale sheaves with transfers, see [MVW, 6.17, 6.18 and 6.19]. The arguments in the proofs of the statements about étale sheaves can easily be extended to proofs for the Nisnevich sheaves.

### 3.2 Homotopy invariant sheaves with transfers

We now introduce the notion of homotopy invariant sheaves (defined below), which will play a central role in the subsequent chapters.

Definition 3.2.1. A presheaf $F$ is homotopy invariant if the map

$$
F(X) \longrightarrow F\left(X \times \mathbb{A}^{1}\right)
$$

induced by the projection $X \times \mathbb{A}^{1} \longrightarrow X$ is an isomorphism. We write $\mathbf{H I}_{p r e}$ for the category of homotopy invariant presheaves with transfers.

Similarly, we define homotopy invariant sheaves, and write $\mathbf{H I}_{\text {ét }}$ (resp. $\mathbf{H I}_{\mathrm{Nis}}$ ) for the full subcategory of homotopy invariant étale sheaves (resp. Nisnevich sheaves) with transfers. We will simply write HI when the underlying pre-topology is understood.

Since $S h_{\text {ét }} C o r$ and $S h_{\text {Nis }} C o r$ are both well-powered, so are $\mathbf{H I}_{\text {ét }}$ and $\mathbf{H I}_{\text {Nis }}$.

Remark 3.2.2. If $F$ is a homotopy invariant presheaf with transfers, then $F_{\text {ét }}$ and $F_{\text {Nis }}$ are homotopy invariant sheaves under the étale and Nisnevich topologies respectively. Together with Proposition 3.1.13, we have the following commutative diagram detailing the subcategories of presheaves on $\mathrm{Sm}_{k}$ and their reflection functors:

where $P S h$ denotes the presheaves on $\mathrm{Sm}_{k}$. In the diagram above, the horizontal arrows represent forgetful functors, and the reflection functors in the first two columns are the restrictions of the reflection functors in the right-most column.

Of the three sheaves mentioned in Example 3.1.11, $\mathbb{Z}$ and $\mathcal{O}^{*}$ are homotopy invariant sheaves, and $\mathcal{O}$ is not. In fact, we can define a large class of homotopy invariant presheaves with transfers with the following construction:

Construction 3.2.3. Let $F$ be a presheaf with transfers. Let $\Delta^{n}$ denote

$$
\operatorname{Spec} k\left[x_{0}, \ldots, x_{n}\right] /\left(1-\sum_{i} x_{i}\right) .
$$

Notice that for each $i$ in $\{0, \ldots, n\}$, there exists a map $\partial_{n, i}: \Delta^{n-1} \longrightarrow \Delta^{n}$ induced by

$$
k\left[x_{0}, \ldots, x_{n}\right] /\left(\sum_{i} x_{i}-1\right) \longrightarrow k\left[x_{0}, \ldots, x_{n-1}\right] /\left(\sum_{i} x_{i}-1\right)
$$

given by

$$
x_{j} \mapsto \begin{cases}x_{j} & \text { if } j<i \\ 0 & \text { if } j=i \\ x_{j-1} & \text { otherwise. }\end{cases}
$$

In particular, $\Delta^{\bullet}$ is a cosimplicial scheme, and $F\left(-\times \Delta^{\bullet}\right)$ is a simplicial presheaf with transfers. Let $C_{*} F$ be the associated cochain complex. That is $\left(C_{*} F(X)\right)^{-n} \stackrel{\text { def }}{=}$ $C_{n} F(X)=F\left(X \times \Delta^{n}\right)$, and the chain map is given by

$$
\partial_{n}^{*} \stackrel{\text { def }}{=} \sum_{i=0}^{n}(-1)^{i} \partial_{n, i}^{*} .
$$

Clearly, if $F$ is a homotopy invariant presheaf, then the complex $C_{*} F$ is exact except at degree 0 . In particular, the inclusion of $F$ as a cochain complex concentrated in degree 0 into $C_{*} F$ is a quasi-isomorphism of cochain complexes of presheaves. In general, for $F$ in PST, write $H^{n} C_{*} F$ for the contravariant functor $U \mapsto H^{n} C_{*} F(U)$. Then $H^{n} C_{*} F$ is homotopy invariant for all $n$ ([MVW, 2.19]).

If $F$ is a sheaf with transfers, then $C_{n} F$ is also a sheaf with transfers for all positive $n$. Therefore, $C_{*} F$ is a cochain complex of sheaves with transfers. In particular, for all $X$ in $\operatorname{Sm}_{k}, C_{*} \mathbb{Z}_{\mathrm{tr}}(X)$ is a cochain complex of sheaves.

Definition 3.2.4. We write $h_{X}^{\text {et }}$ (resp., $h_{X}^{\text {Nis }}$ ) for the etale (resp., Nisnevich) sheaf associated to $H^{0} C_{*} \mathbb{Z}_{\text {tr }}(X)$. In the case where the pre-topology is understood, we will omit the superscript, and simply write $h_{X}$ for the associated sheaf.

Remark 3.2.5. Recall that two morphisms $f, g: X \longrightarrow Y$ in Cor are $\mathbb{A}^{1}$-homotopic if there exists some $h$ in $\operatorname{Cor}\left(X \times \mathbb{A}^{1}, Y\right)$ such that $\left.h\right|_{X \times 0}=f$ and $\left.h\right|_{X \times 1}=g$. We say that $f: X \longrightarrow Y$ is an $\mathbb{A}^{1}$-homotopy equivalence if there exists a $g: Y \longrightarrow X$ so that $f g$ is homotopic to the identity on $Y$, and $g f$ is homotopic to the identity on $X$.

If $X$ and $Y$ are homotopy equivalent, it is not true in general that $\mathbb{Z}_{\operatorname{tr}}(X)$ is isomorphic to $\mathbb{Z}_{\mathrm{tr}}(Y)$. For example, $\mathbb{Z}$ is obviously not isomorphic to $\mathbb{Z}_{\mathrm{tr}}\left(\mathbb{A}^{1}\right)$. However, $C_{*} \mathbb{Z}_{\operatorname{tr}}(X)$ is quasi-isomorphic to $C_{*} \mathbb{Z}_{\operatorname{tr}}(Y)$ (see [MVW, 2.26]). Therefore, $h_{X}$ and $h_{Y}$ are isomorphic sheaves with transfers.

Remark 3.2.6. We note that all results of this chapter hold for $\operatorname{PST}(R)$, which are presheaves with transfers with values in $R$-modules, where $R$ is some commutative unital ring. In particular, $R_{\mathrm{tr}}(X)$ is an étale/Nisnevich sheaf, for every $X$ in $\operatorname{Sm}_{k}$.

We conclude this chapter with an endofunctor on the category HI that will play an important role in the construction of filtrations on HI.

Definition 3.2.7. Let $F$ be a homotopy invariant presheaf with transfers. Write $F_{-1}(X)$ for the cokernel of $F\left(X \times \mathbb{A}^{1}\right) \longrightarrow F\left(X \times\left(\mathbb{A}^{1}-0\right)\right)$. If $F$ is a Nisnevich sheaf with transfers, then $F_{-1}$ is again a Nisnevich sheaf with transfers by [MVW, 23.5]. We call $F_{-1}$ the the contraction of $F$. We will write $F_{-n+1}$ for $\left(F_{-n}\right)_{-1}$.

If $F$ is homotopy invariant, then $F_{-1}$ is also a homotopy invariant. Furthermore, $F\left(X \times\left(\mathbb{A}^{1}-0\right)\right)$ splits into $F(X) \oplus F_{-1}(X)$. Thus, if $F$ is a sheaf, then $F_{-1}$ is also a sheaf. In fact, $F \mapsto F_{-1}$ defines an endofunctor on the category of homotopy invariant sheaves with transfers.

Proposition 3.2.8 ([Dég08] 3.4.3). The functor $F \mapsto F_{-1}$ is exact.

## Chapter 4

## The Derived Category of Motives

In this chapter, we define the derived category of motives $\mathbf{D} \mathbf{M}^{\text {eff,- }}$, and show that it is equipped with an additive symmetric monoidal structure with a partial internal hom (defined in Definition 4.2.1) that will be used to construct the slice filtration in Section 5 (see Remark 4.2.11).

To do this, we first define the bounded above derived category $\mathbf{D}^{-}$ShCor of Nisnevich sheaves, and define $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ to be the localization of $\mathbf{D}^{-} S h C o r$ by a class of morphisms in $\mathbf{D}^{-} S h C$ or called $\mathbb{A}^{1}$-weak equivalences. We then show that $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$ is in fact equivalent as a category to the subcategory of $\mathbf{D}^{-}$ShCor with homotopy invariant cohomology.

We also show that $\mathbf{D}^{-}$PST is equipped with tensor and internal hom operations on which induce a symmetric monoidal structure on $\mathbf{D} \mathbf{M}^{\text {eff,- }}$. For the remainder of the chapter, unless stated otherwise, all sheaves are Nisnevich sheaves. We will drop the "Nis", and simply write ShCor for the category of Nisnevich sheaves with transfers. This chapter is taken from Lectures 8, 9 and 14 of [MVW].

### 4.1 Derived Category of Motives

First consider the category PST. By Yoneda, for $X$ in $\operatorname{Sm}_{k}$ and $F$ in PST,

$$
\operatorname{Hom}_{\mathbf{P S T}}\left(\mathbb{Z}_{\mathrm{tr}}(X), F\right)=F(X) .
$$

It follows that $\mathbb{Z}_{\mathrm{tr}}(X)$ is projective for every $X$ in $\mathrm{Sm}_{k}$. Since direct sums of projectives are projective, $\oplus_{i} \mathbb{Z}_{\mathrm{tr}}\left(X_{i}\right)$ is also projective for any arbitrary collection $\left\{Z_{i}\right\}$. Furthermore, for $F$ in PST, there exists a surjection

$$
\begin{equation*}
\bigoplus_{X} \bigoplus_{x \in F(X)} \mathbb{Z}_{\operatorname{tr}}(X) \xrightarrow{x} F \tag{4.1.1}
\end{equation*}
$$

Hence, the category PST has enough projectives. Thus, we may define the bounded above derived category $\mathbf{D}^{-} \mathbf{P S T}$ of the abelian category PST as the homotopy category of cochain complexes of projective objects in PST that are bounded above (see [Wei94, 10.4.8]). To construct the bounded above category of Nisnevich sheaves with transfers, we first need the following notion of a thick subcategory:

Definition 4.1.2. A full additive subcategory $\mathscr{W}$ of a derived category $\mathbf{D}$ is thick if it satisfies the following conditions:

1. if $A \longrightarrow B \longrightarrow C \longrightarrow A[1]$ is a distinguished triangle, then any two of $A, B, C$ is in $\mathscr{W}$, then so is the third.
2. if $A \oplus B$ is an object of $\mathscr{W}$, then $A$ and $B$ are both objects of $\mathscr{W}$.

If $\mathscr{W}$ is a thick subcategory of a derived category $\mathbf{D}$, then we can define a quotient triangulated category $\mathbf{D} / \mathscr{W}$. Let $\mathscr{S}$ be the set of maps whose cone is in $\mathscr{W}$. Then $\mathscr{S}$ is a saturated multiplicative system in the sense that $\mathscr{S}$ contains the identity, is closed under composition, and if $f g \in \mathscr{S}$, then $f$ and $g$ are both in $\mathscr{S}$. Define $\mathbf{D} / \mathscr{W}$ to be the localization $\mathbf{D}\left[\mathscr{S}^{-1}\right]$ (see $\left.[\operatorname{Verd} 96]\right)$.

Let $\mathscr{W}_{\text {Nis }}$ be the system of morphisms between cochain complexes in $\mathbf{D}^{-}$PST inducing quasi-isomorphisms on the associated complex of Nisnevich sheaves. Since $\mathscr{W}_{\text {Nis }}$ are the morphisms whose cone is in a thick subcategory, $\mathscr{W}_{\text {Nis }}$ is saturated multiplicative system. We will write $\mathbf{D}^{-}$ShCor, or more simply $\mathbf{D}^{-} \mathbf{S T}$, for the bounded above derived category of Nisnevich sheaves with transfers, which is equivalent to the category obtained from $\mathbf{D}^{-}$PST by localizing with respect to $\mathscr{W}_{\text {Nis }}$. We now define $\mathbf{D M}^{\text {eff,- }}$, the derived category of effective motives.

Definition 4.1.3. Let $\mathscr{W}_{\mathbb{A}}$ be the thick subcategory of $\mathbf{D}^{-} \mathbf{S T}$ generated by the cones of $\mathbb{Z}_{\mathrm{tr}}\left(X \times \mathbb{A}^{1}\right) \longrightarrow \mathbb{Z}_{\mathrm{tr}}(X)$ for every $X$ in $\mathrm{Sm}_{k}$, and closed under direct sums that exist in $\mathbf{D}^{-} \mathbf{S T}$. Write $\mathscr{S}_{\mathbb{A}}$ for the maps whose cone is in $\mathscr{W}_{\mathbb{A}}$. We say that a map $f$ in $\mathbf{D}^{-} \mathbf{S T}$ is an $\mathbb{A}^{1}$-weak equivalence if $f \in \mathscr{S}_{\mathbb{A}}$.

We write $\mathbf{D M}{ }^{\text {eff,- }}$ for the localization $\mathbf{D}^{-} \mathbf{S T}\left[\mathscr{S}_{\mathbb{A}}^{-1}\right]$. The category that we have just defined is the derived category of effective motives, whose objects are called motives.

While we have defined $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ as a localization of $\mathbf{D}^{-}$by the $\mathbb{A}^{1}$-weak equivalences, we can identify $\mathbf{D M}{ }^{\text {eff,-- }}$ with a subcategory of $\mathbf{D}^{-} \mathbf{S T}$.

Definition 4.1.4. Let $F^{*}$ be a cochain regarded as an object of $\mathbf{D}^{-} \mathbf{S T}$. We say that $F^{*}$ is $\mathbb{A}^{1}$-local if $\operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(-, F^{*}\right)$ sends $\mathbb{A}^{1}$-weak equivalences to isomorphisms. We write $\mathscr{L}$ for the full subcategory of $\mathbb{A}^{1}$-local objects in $\mathbf{D}^{-} \mathbf{S T}$.

Proposition 4.1.5 gives a good characterization of the category $\mathscr{L}$.
Proposition 4.1.5 ([MVW] Prop. 14.8, Cor. 14.9). For $F^{*}$ in $\mathbf{D}^{-} \mathbf{S T}, F^{*} \in \mathscr{L}$ if and only if $a_{\text {Nis }}\left(H^{n} F^{*}\right)$ is homotopy invariant for every integer $n$. In particular, we can identify $\mathscr{L}$ with the full subcategory of complexes in $\mathbf{D}^{-} \mathbf{S T}$ with homotopy invariant cohomology presheaves.

Definition 4.1.6. For $F^{*}$ a bounded above cochain complex of sheaves with transfers, let $C F^{*}$ denote the direct sum total complex of the double complex $C_{*} F^{*}$. Here, the $(p, q)$ spot of the double complex $C_{*} F^{*}$ is $C_{-p} F^{q}$. Therefore, $C F^{*}$ again is an object of $\mathrm{D}^{-}$ST.

Since $F^{*}$ is bounded above, by shifting sufficiently, we may assume that $F^{n}=0$ for $n>0$. Therefore, indexing the double complex cohomologically, $C_{*} F^{*}$ is a third quadrant double complex. Filtering the double complex $C_{p} F^{q}$ by the second index $q$, we obtain a third quadrant spectral sequence converging to the cohomology of $C F^{*}$ :

$$
E_{1}^{p, q}=H^{p}\left(C_{*} F^{q}\right) \Rightarrow H^{p+q}\left(C F^{*}\right) .
$$

Since the cohomology presheaves $H^{p}\left(C_{*} F^{q}\right)$ are homotopy invariant for all $p$ and $q$ (see [MVW, 2.19]), the terms in the first page of the spectral sequence are all homotopy invariant. It follows that $C F^{*}$ is in $\mathscr{L}$. The following proposition relates the construction defined above and the category $\mathscr{L}$.

Proposition 4.1.7. The functor $C_{*}: \mathbf{D}^{-} \mathbf{S T} \longrightarrow \mathscr{L}$ is a left adjoint to the inclusion of $\mathscr{L} \longleftrightarrow \mathbf{D}^{-} \mathbf{S T}$.

Proof. There is a canonical map from $F^{*} \longrightarrow C F^{*}$, given by the inclusion of $F_{i}=$ $C_{0} F_{i} \longrightarrow \bigoplus_{p+q=i} C_{-p} F^{q}$. This map is a $\mathbb{A}^{1}$-weak equivalence (see [MVW, 14.4]).

Therefore, for any $L^{*}$ in $\mathscr{L}$ and $F^{*}$ in $\mathbf{D}^{-} \mathbf{S T}$,

$$
\operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(F^{*}, L^{*}\right) \cong \operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(C F^{*}, L^{*}\right)=\operatorname{Hom}_{\mathscr{L}}\left(C F^{*}, L^{*}\right)
$$

There is a canonical functor $\pi: \mathbf{D}^{-} \mathbf{S T} \longrightarrow \mathbf{D M}^{\text {eff,- }}$, given by sending an object of $\mathbf{D}^{-} \mathbf{S T}$ to its corresponding object in $\mathbf{D M}^{\text {eff,-- }}$. Its restriction to $\mathscr{L}$ defines a functor from $\mathscr{L}$ to $\mathbf{D M}^{\text {eff,- }}$.

Furthermore, we can define a map from $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ to $\mathscr{L}$. Notice that if $F^{*}$ and $F^{\prime *}$ are $\mathbb{A}^{1}$-weak equivalent, then transitivity implies that $C F^{*}$ is $\mathbb{A}^{1}$-weak equivalent to $C F^{*}$. It follows that the functor that sends $F^{*}$ to $C F^{*}$ lifts to a functor from $\mathbf{D M}{ }^{\text {eff,- }} \longrightarrow \mathscr{L}$. Let $C_{*}$ denote the induced functor on $\mathbf{D M}^{\text {eff,- }}$.

Theorem 4.1.8. The functor $\pi: \mathscr{L} \longrightarrow \mathbf{D M}^{\mathrm{eff},-}$ is an equivalence of categories, with quasi-inverse $C_{*}$.

Proof. The fact that $\pi$ is an equivalence is established in [MVW, 14.11]. Furthermore, given $M$ in $\mathbf{D M}{ }^{\text {eff,-- }}$, then $M$ is represented by some bounded above complex $F^{*}$. In turn, $F^{*}$ is isomorphic (in $\mathbf{D M}{ }^{\text {eff,-- }}$ ) to $C F^{*}$, which is in the essential image of $\pi$, and define $C_{*} M=C F^{*}$.

For the second statement, it suffices at this point to show that $C_{*} \pi$ is naturally isomorphic to the identity on $\mathscr{L}$. This follows from the fact that if $F^{*}$ is $\mathbb{A}^{1}$-local, then $C F^{*}$ is isomorphic to $F^{*}$ (see [MVW, 14.9]).

Example 4.1.9. An important class of examples is provided by the geometric objects. Let $X$ be a smooth scheme. Then we may regard $\mathbb{Z}_{\mathrm{tr}}(X)$ as a cochain complex of Nisnevich sheaf with transfers concentrated in degree 0 (see Example 3.1.12); it represents an object in $\mathbf{D}^{-} \mathbf{S T}$, and thus also an object in $\mathbf{D M}{ }^{\text {eff,-- }}$. We call the full triangulated subcategory of $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ generated by $\mathbb{Z}_{\mathrm{tr}}(X)$, as $X$ ranges over all smooth schemes, the effective geometric motives, which we represent by $\mathbf{D} \mathbf{M}_{g m}^{\text {eff,- }}$. We write $M(X)$ for the class of $\mathbb{Z}_{\mathrm{tr}}(X)$ in $\mathbf{D M}^{\text {eff,- }}$.

On the other hand, $C_{*} \mathbb{Z}_{\operatorname{tr}}(X)$ represents an object in $\mathscr{L}$, and we can similarly define the geometric objects of $\mathscr{L}$ as those belonging to the thick subcategory generated by the
cochain complexes $C_{*} \mathbb{Z}_{\mathrm{tr}}(X)$, for $X$ in $\mathrm{Sm}_{k}$. By Theorem 4.1.8, $\mathbf{D M}_{g m}^{\mathrm{eff},-}$ corresponds to the geometric objects of $\mathscr{L}$.

### 4.2 Triangulated Monoidal Structure on DM $^{\text {eff,- }}$

Recall from [Kelly82, 1.13] and [MVW, 8A.1] the notion of a symmetric closed monoidal structure generalized to the setting of a triangulated category:

Definition 4.2.1. Let $(\mathbf{D}, \otimes, \mathbb{1})$ be a triangulated category. We say that $\mathbf{D}$ is a tensor triangulated category if there exists a pair of natural isomorphisms

$$
(M[1]) \otimes N \xrightarrow{l_{M, N}}(M \otimes N)[1]{\overleftarrow{r_{M, N}}} M \otimes(N[1])
$$

such that $(\mathbf{D}, \otimes)$ satisfies the axioms of a symmetric monoidal category, and the following two conditions hold

1. For any distinguished triangle $M^{\prime} \longrightarrow M \longrightarrow M^{\prime \prime} \xrightarrow{\delta} M^{\prime}[1]$, and any $N$ in $\mathbf{D}$, the following triangles are distinguished

$$
\begin{aligned}
& M^{\prime} \otimes N \longrightarrow M \otimes N \longrightarrow M^{\prime \prime} \otimes N \xrightarrow{l(\delta \otimes D)}\left(M^{\prime} \otimes N\right)[1] \\
& N \otimes M^{\prime} \longrightarrow N \otimes M \longrightarrow N \otimes M^{\prime \prime} \xrightarrow{r(D \otimes \delta)}\left(N \otimes M^{\prime}\right)[1]
\end{aligned}
$$

2. For any $M$ and $N$ in $\mathbf{D}$, the following anti-commutes, i.e., $r l=-l r$ :

We say that $(\mathbf{D}, \otimes)$ is an additive symmetric monoidal category if

$$
\left(\bigoplus M_{i}\right) \otimes N=\bigoplus_{i}\left(M_{i} \otimes N\right)
$$

for all $N$ in $\mathbf{D}$ and all families $\left\{M_{i}\right\}$ of objects of $\mathbf{D}$ such that the direct sum $\oplus_{i} M_{i}$ exists in $\mathbf{D}$.

Recall that for a symmetric monoidal category $(\mathscr{C}, \otimes, \mathbb{1})$, an internal hom in $\mathscr{C}$ is a bifunctor

$$
\underline{\text { Hom }}: \mathscr{C}^{\mathrm{op}} \times \mathscr{C} \longrightarrow \mathscr{C},
$$

such that for all $C$ in $\mathscr{C}$, the endofunctor $\operatorname{Hom}(C,-)$ is right adjoint to the functor $-\otimes C$; in this case, we say that $\mathscr{C}$ is a closed monoidal category. Not every symmetric monoidal category admits an internal hom, although it is possible for $-\otimes C$ to admit right adjoints for some objects $C$ of $\mathscr{C}$. We introduce the following definition to describe this notion:

Definition 4.2.2. For a symmetric monoidal category $(\mathscr{C}, \otimes, \mathbb{1})$, we say that $\mathscr{C}$ has a partial internal hom if there exists a full subcategory $\mathscr{C}^{\text {rep }}$ of $\mathscr{C}$ containing $\mathbb{1}$, and a
 adjoint to $\underline{\operatorname{Hom}}(F,-)$.

We call $\mathscr{C}^{\text {rep }}$ the semi-representable objects of $\mathscr{C}$, and Hom the partial internal hom in $\mathscr{C}$. We call the pair (Hom, $\mathscr{C}^{\text {rep }}$ ) the partial internal hom structure on $\mathscr{C}$.

Following [MVW], we show that $\mathbf{D M}^{\text {eff,-- }}$ is equipped with an additive symmetric monoidal structure and a partial internal hom structure. Let us first define the tensor and internal hom operators on PST. By Yoneda Lemma, $\operatorname{Hom}_{\mathbf{P S T}}\left(\mathbb{Z}_{\mathrm{tr}}(X), \mathbb{Z}_{\mathrm{tr}}(Y)\right) \cong$ $\operatorname{Cor}(X, Y)$ for all $X$ and $Y$ in $\mathrm{Sm}_{k}$, i.e., we can identify a morphism between representable presheaves as a finite correspondence. The tensor structure will be determined by the following requirements.

1. $\mathbb{Z}_{\mathrm{tr}}(X) \otimes^{\operatorname{tr}} \mathbb{Z}_{\mathrm{tr}}(Y) \stackrel{\text { def }}{=} \mathbb{Z}_{\mathrm{tr}}(X \times Y)$,
2. for each map $\varphi$ in $\operatorname{Hom}_{\mathbf{P S T}}\left(\mathbb{Z}_{\operatorname{tr}}(X), \mathbb{Z}_{\mathrm{tr}}(Y)\right)$, let $W$ be its associated finite correspondence in $\operatorname{Cor}(X, Y)$. Then $\varphi \otimes \mathbb{Z}_{\mathrm{tr}}(Z): \mathbb{Z}_{\mathrm{tr}}(X) \otimes^{\operatorname{tr}} \mathbb{Z}_{\mathrm{tr}}(Z) \longrightarrow \mathbb{Z}_{\mathrm{tr}}(Y) \otimes^{\operatorname{tr}}$ $\mathbb{Z}_{\mathrm{tr}}(Z)$ corresponds to the finite correspondence $W \times Z$.

It is clear that we can extend the bifunctor $\otimes^{\text {tr }}$ to arbitrary direct sums of representable presheaves.

Next, for arbitrary presheaves with transfers $F, G$, let $P^{*} \longrightarrow F$ and $Q^{*} \longrightarrow G$ be resolutions by direct sums of representable functors of $F$ and $G$ respectively. We write
$F \otimes^{\mathbb{L}} G$ for the total complex of the double complex $P^{*} \otimes^{\operatorname{tr}} Q^{*}$. By the Comparison Theorem [Wei94, 2.26], any two projective resolutions are chain homotopy equivalent. Therefore, it is easy to see that up to chain homotopy equivalence, this is independent of the choice of $P^{*}$ and $Q^{*}$.

In particular, $H^{0}\left(F \otimes^{\mathbb{L}} G\right)$ is well-defined. Define the tensor operation on PST to be

$$
F \otimes G \stackrel{\text { def }}{=} H^{0}\left(F \otimes^{\mathbb{L}} G\right)
$$

and define the internal hom presheaf by

$$
\underline{\operatorname{Hom}}(F, G): X \mapsto \operatorname{Hom}_{\mathbf{P S T}}\left(F \otimes \mathbb{Z}_{\mathrm{tr}}(X), G\right) .
$$

These operations define a closed monoidal structure on PST. That is, for all $F$ in PST, the functor $F \otimes^{\mathbb{L}}-$ is adjoint to $\underline{\operatorname{Hom}}(-, F)$ (see [MVW, 8.3]).

Remark 4.2.3. Notice that the $\otimes$ structure defined is not the usual tensor product on presheaves of abelian groups. In particular, $\mathbb{Z}_{\mathrm{tr}}(X)(Z) \otimes_{\mathbb{Z}} \mathbb{Z}_{\mathrm{tr}}(Y)(Z) \neq \mathbb{Z}_{\mathrm{tr}}(X \times Y)(Z)$, where $\otimes_{\mathbb{Z}}$ denotes the usual tensor product of abelian groups.

We now extend $\otimes$ to $\mathbf{D}^{-} \mathbf{P S T}$. To do so, let $F^{*}$ represent a bounded above cochain complex of presheaves with transfers. By [Wei94, 10.5.6], $F^{*}$ is quasi-isomorphic to a projective complex $P^{*}$. In fact, we may assume that $P^{*}$ is a complex such that $P^{i}$ is a direct sum of representable presheaves.

Define $F^{*} \otimes^{\mathbb{L}} G^{*}$ to be the direct sum total complex associated with $P^{*} \otimes Q^{*}$, where $P^{*}$ and $Q^{*}$ are projective resolutions of $F^{*}$ and $G^{*}$ respectively. Notice that $F^{*} \otimes^{\mathbb{L}} G^{*}$ is defined up to unique quasi-isomorphism. In particular, $\otimes^{\mathbb{L}}$ is defined up to quasiisomorphism as a bifunctor on $\mathbf{D}^{-}$PST. Indeed, let $F^{*}$ and $F^{\prime *}$ be two quasi-isomorphic bounded above complexes in PST. Then for any bounded above cochain $G^{*}$ in PST, $F^{*} \otimes^{\mathbb{L}} G^{*} \cong F^{\prime *} \otimes^{\mathbb{L}} G^{*}$. (see [MVW, 8.7]) To show that $\mathbf{D}^{-} \mathbf{P S T}$ is equipped with a tensor triangulated structure, we make the following observation.

Let $\mathrm{Cor}^{\oplus}$ denote the closure under direct sum of representable presheaves in PST. This is an additive category equipped with an additive symmetric monoidal structure. By [MVW, 8A.4], we see that the homotopy category $\mathbf{K}^{-}\left(\mathrm{Cor}^{\oplus}\right)$ is a tensor triangulated
categegory. By arguments similar to those in [Wei94, 10.4.8], $\mathbf{D}^{-}$PST is equivalent as a category to $\mathbf{K}^{-}\left(\mathrm{Cor}^{\oplus}\right)$. It follows that $\mathbf{D}^{-} \mathbf{P S T}$ is also a tensor triangulated category.

Next, we show that the tensor structure is preserved under Nisnevich sheafification.
Definition 4.2.4. Let $F, G$ be Nisnevich sheaves with transfers. Define $F \otimes_{\text {Nis }}^{\mathrm{tr}} G$ to be the Nisnevich sheafification of the presheaf $F \otimes^{\operatorname{tr}} G$. That is,

$$
F \otimes_{\mathrm{Nis}}^{\operatorname{tr}} G \stackrel{\text { def }}{=} a_{\mathrm{Nis}}\left(F \otimes^{\operatorname{tr}} G\right)
$$

where $a_{\text {Nis }}$ is the Nisnevich sheafification. We can extend $\otimes_{\text {Nis }}^{\operatorname{tr}}$ to cochain complexes of Nisnevich sheaves. Let $F^{*}$ and $G^{*}$ be bounded above cochain complexes of Nisnevich sheaves with transfers. Define $F^{*} \otimes_{\mathrm{N} i \mathrm{~s}}^{\mathbb{L}} G^{*}$ to be the Nisnevich sheafification of the complex $F^{*} \otimes^{\mathbb{L}} G^{*}$ :

$$
F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} G^{*} \stackrel{\text { def }}{=} a_{\mathrm{Nis}}\left(F^{*} \otimes^{\mathbb{L}} G^{*}\right)
$$

This is well-defined up to quasi-isomorphism.
Remark 4.2.5. Fix $F$ and $G$ sheaves with transfers, and let $P^{*}$ and $Q^{*}$ be resolutions by sums of representables of $F^{*}$ and $G^{*}$ respectively. Since $a_{\text {Nis }}$ is exact, $a_{\text {Nis }}\left(F \otimes^{\mathbb{L}} G\right)=$ $a_{\text {Nis }}\left(\operatorname{Tot}\left(P^{*} \otimes^{\operatorname{tr}} Q^{*}\right)\right)=\operatorname{Tot}\left(P^{*} \otimes_{\text {Nis }}^{\operatorname{tr}} Q^{*}\right)$.

We claim that $\left(\mathbf{D}^{-} \mathbf{S T}, \otimes_{\text {Nis }}^{\mathbb{L}}\right)$ is an additive symmetric monoidal triangulated category. The proof depends on the following lemma.

Lemma 4.2.6 ([MVW] Prop. 8A.7). Let $\mathbf{D}$ be a tensor triangulated category, and let $\mathscr{W}$ be a collection of maps in $\mathbf{D}$ that is closed under $-\otimes N$ for every $N$ in $\mathbf{D}$, i.e., if $M \longrightarrow M^{\prime}$ is in $\mathscr{W}$ then so is $M \otimes N \longrightarrow M^{\prime} \otimes N$. Then the localization $\mathscr{W}^{-1}$ is also a tensor triangulated category.

To proceed, we note that if $F^{*}$ is quasi-isomorphic to $F^{\prime *}$, then for every bounded above complex $G^{*}$ of sheaves with transfers, $F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} G^{*}$ is quasi-isomorphic to $F^{\prime *} \otimes_{\mathrm{Nis}}^{\mathbb{L}} G^{*}$ (see [MVW, 8.16]). Therefore, $\otimes_{\mathrm{N} \text { is }}^{\mathbb{L}}$ is a well-defined bifunctor on $\mathbf{D}^{-} \mathbf{S T}$. Finally, observe that $\mathbf{D}^{-} \mathbf{S T}$ is equivalent to the category obtained from $\mathbf{D}^{-} \mathbf{P S T}$ by formally inverting morphisms of the form $F^{*} \longrightarrow F^{\prime *}$ such that $a_{\text {Nis }}\left(F^{*}\right) \longrightarrow a_{\text {Nis }}\left(F^{\prime *}\right)$ is an quasi-isomorphism. We obtain a tensor triangulated structure on $\mathbf{D}^{-}$ST by Lemma 4.2.6.

In fact, the same argument shows that $\mathbf{D M}^{\text {eff,-- }}$ is equipped with a tensor triangulated structure. Recall that $\mathbf{D M}{ }^{\text {eff,-- }}$ is equivalent to the category obtained from $\mathbf{D}^{-} \mathbf{S T}$ by formally inverting the $\mathbb{A}^{1}$-weak equivalences. If $\varphi: F^{*} \longrightarrow F^{\prime *}$ is an $\mathbb{A}^{1}$-weak equivalence, then by [MVW, 9.5] for all $G^{*}$ in $\mathbf{D}^{-} \mathbf{S T}, \varphi \otimes_{\mathrm{Nis}}^{\mathbb{L}} G^{*}: F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} G^{*} \longrightarrow F^{\prime *} \otimes_{\mathrm{Nis}}^{\mathbb{L}} G^{*}$ is an $\mathbb{A}^{1}$-weak equivalence. Hence, $\otimes_{\text {Nis }}^{\mathbb{L}}$ induces a triangulated tensor product on $\mathbf{D M}^{\mathrm{eff},-}$. We represent the tensor product on $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ by $\otimes^{L}$.

There also exists a tensor operation on $\mathscr{L}$, which is different from the one defined on its parent category $\mathbf{D}^{-} \mathbf{S T}$. For $F^{*}, G^{*}$ in $\mathscr{L}$, we define $F^{*} \otimes \mathscr{L} G^{*}$ to be the direct sum total complex

$$
\operatorname{Tot}^{\oplus} C\left(F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} G^{*}\right)
$$

The tensor product $\otimes_{\mathscr{L}}$ is a triangulated tensor product by [MVW, 14.11], and the categorical equivalence $\pi: \mathscr{L} \longrightarrow \mathbf{D M}^{\text {eff,- }}$ in Theorem 4.1.8 is an equivalence of tensor triangulated categories.

Let us now define the partial internal hom structure on $\mathbf{D M}^{\text {eff,-- }}$. We will do this by defining a partial internal hom structure on $\mathscr{L}$. This, in turn, is obtained from the partial internal hom structure on $\mathbf{D}^{-} \mathbf{S T}$.

Definition 4.2.7. Fix a bounded above complex of Nisnevich sheaves $B^{*}$ and an injective Cartan-Eilenberg resolution $B^{*} \longrightarrow I^{*}$, which exists by [MVW, 6.19]. For $X$ in $\mathrm{Sm}_{k}$, define $\underline{\mathrm{RHom}}\left(\mathbb{Z}_{\mathrm{tr}}(X), B^{*}\right)$ to be the complex of sheaves given by

$$
\underline{\operatorname{RHom}}\left(\mathbb{Z}_{\mathrm{tr}}(X), B^{*}\right)(U)=\operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}^{*}\left(\mathbb{Z}_{\mathrm{tr}}(X \times U), I^{*}\right)
$$

Notice that the cochain complex $\operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}^{*}\left(\mathbb{Z}_{\operatorname{tr}}(X \times U), I^{*}\right)$ is defined up to unique quasi-isomorphism. Furthermore, by [Voe00, 3.2.9], $\mathbf{H}^{k} \underline{\operatorname{RHom}}\left(\mathbb{Z}_{\mathrm{tr}}(X), B^{*}\right)=0$ for all $k>\operatorname{dim} X+l$, where $l$ is the smallest index such that $\mathbf{H}^{0} B^{*}$ has non-vanishing cohomology. Hence $\underline{\text { RHom }}\left(\mathbb{Z}_{\operatorname{tr}}(X), B^{*}\right)$ is an object of $\mathbf{D}^{-} \mathbf{S T}$. We can extend RHom in the first factor to the thick subcategory $\mathbf{D}^{-} \mathbf{S T}{ }^{\text {rep }}$ of $\mathbf{D}^{-} \mathbf{S T}$ generated by the sheaves $\mathbb{Z}_{\mathrm{tr}}(X)$ regarded as cochain complexes concentrated in degree 0 .

The lemma below follows from the construction of RHom.

Lemma 4.2.8. For all $X$ in $\mathrm{Sm}_{k}$, and all $F^{*}, G^{*}$ in $\mathbf{D}^{-} \mathbf{S T}$, we have the following adjunction

$$
\operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} \mathbb{Z}_{\mathrm{tr}}(X), G^{*}\right) \cong \operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(F^{*}, \underline{\operatorname{RHom}}\left(\mathbb{Z}_{\mathrm{tr}}(X), G^{*}\right)\right)
$$

We now define the partial internal hom structure for $\mathscr{L}$. By [MVW, 14.12], if a bounded above cochain complex $F^{*}$ in $\mathbf{D}^{-} \mathbf{S T}$ is $\mathbb{A}^{1}$-local, then for all $X$ in $\mathrm{Sm}_{k}$, the cochain complex $\underline{\operatorname{RHom}}\left(\mathbb{Z}_{\mathrm{tr}}(X), F^{*}\right)$ is also $\mathbb{A}^{1}$-local.

Definition 4.2.9. Fix $X$ in $\operatorname{Sm}_{k}$, and let $F^{*}$ be a bounded above $\mathbb{A}^{1}$-local complex. We define $\underline{\mathrm{RHom}}_{\mathscr{L}}\left(C_{*} \mathbb{Z}_{\mathrm{tr}}(X), F^{*}\right)$ to be the chain complex of sheaves given by

$$
\underline{\operatorname{RHom}}_{\mathscr{L}}\left(C_{*} \mathbb{Z}_{\mathrm{tr}}(X), F^{*}\right)(U) \stackrel{\text { def }}{=} \operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}^{*}\left(C_{*} \mathbb{Z}_{\mathrm{tr}}(X \times U), F^{*}\right)
$$

As in Definition 4.2.7, we may extend the definition of RHom $_{\mathscr{L}}$ in the first factor to all objects in the thick subcategory of $\mathscr{L}$ generated by the cochain complexes $C \mathbb{Z}_{\operatorname{tr}}(X)$.

Recall from Proposition 4.1.7 that the functor $F^{*} \mapsto C F^{*}$ is left adjoint to the inclusion of $\mathscr{L}$. Hence, by the definition of $\underline{\mathrm{RHom}}_{\mathscr{L}}$ above, we have the following equality of endofunctors of $\mathscr{L}$ :

$$
\underline{\mathrm{RHom}}_{\mathscr{L}}\left(C \mathbb{Z}_{\mathrm{tr}}(X),-\right)=\underline{\mathrm{RHom}}\left(\mathbb{Z}_{\mathrm{tr}}(X),-\right) .
$$

To see that $\underline{\text { RHom }}_{\mathscr{L}}$ defines a partial internal hom in $\mathscr{L}$, we need to verify that for all
 be bounded above $\mathbb{A}^{1}$-local complexes. We have the following chain of isomorphisms:

$$
\begin{aligned}
& \operatorname{Hom}_{\mathscr{L}}\left(F^{*} \otimes \mathscr{L} C_{*} \mathbb{Z}_{\mathrm{tr}}(X), G^{*}\right) \stackrel{(1)}{=} \operatorname{Hom}_{\mathbf{D}^{-}} \mathbf{s T}\left(C\left(F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} C_{*} \mathbb{Z}_{\mathrm{tr}}(X)\right), G^{*}\right) \\
& \stackrel{(2)}{\cong} \operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{K}} \mathbb{Z}_{\mathrm{tr}}(X), G^{*}\right) \\
& \stackrel{(3)}{=} \operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(F^{*}, \underline{\mathrm{RHom}}\left(\mathbb{Z}_{\mathrm{tr}}(X), G^{*}\right)\right. \\
& \stackrel{(4)}{\cong} \operatorname{Hom}_{\mathscr{L}}\left(F^{*}, \underline{\mathrm{RHom}}_{\mathscr{L}}\left(C_{*} \mathbb{Z}_{\mathrm{tr}}(X), G^{*}\right)\right),
\end{aligned}
$$

where $F^{*}$ and $G^{*}$ are bounded above $\mathbb{A}^{1}$-local complexes, and $X$ is an arbitrary smooth scheme. The equality in (1) follows from the definition of $\otimes \mathscr{L} ;(2)$ and (4) follow from
the adjunction introduced in Proposition 4.1.7; and (3) follows from the adjunction established in Lemma 4.2.8.

Via the categorical equivalence between $\mathscr{L}$ and $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$, there exists a partial internal hom structure on $\mathbf{D M}^{\text {eff,--}}$. We write $\otimes^{L}$ and $\underline{\text { RHom }}_{\mathbf{D M}^{\text {eff,-- }}}$ for the tensor and partial internal hom operators respectively. Here, the semi-representable objects are the geometric motives $\mathbf{D} M_{g m}^{\text {eff,-- }}$ defined in Example 4.1.9. We have just established the proposition below:

Proposition 4.2.10 ([MVW] 14.12). Let $\otimes^{L}$ and $\underline{\text { RHom }}_{\text {DM }^{\text {eff,-- }}}$ be given as above. Then for all $M$ in $\mathbf{D M}_{g m}^{\text {eff,-- }},-\otimes^{L} M$ is left adjoint to $\underline{R H o m}_{\mathbf{D M}^{\text {eff,- }}}(M,-)$.

Remark 4.2.11. Notice that $\underline{\text { RHom }}$ and $\underline{\operatorname{RHom}}_{\mathscr{L}}$ do not define a closed monoidal structure on their respective categories, as they are only defined on the geometric objects.

### 4.3 The motivic complex $\mathbb{Z}(n)$

We now introduce an important set of objects in $\mathbf{D} \mathbf{M}^{\text {eff,- }}$. Let $\mathbb{Z}_{\mathrm{tr}}\left(\mathbb{G}_{m}\right)$ denote the cokernel of

$$
\mathbb{Z}=\mathbb{Z}_{\mathrm{tr}}(\operatorname{Spec} k) \longrightarrow \mathbb{Z}_{\mathrm{tr}}\left(\mathbb{A}^{1}-0\right)
$$

given by $k\left[x, x^{-1}\right] \longrightarrow k$, induced by $x \mapsto 1$. Since $k \longrightarrow k\left[x, x^{-1}\right]$ defines a splitting $\mathbb{Z}_{\mathrm{tr}}\left(\mathbb{A}^{1}-0\right) \cong \mathbb{Z}_{\mathrm{tr}}\left(\mathbb{G}_{m}\right) \oplus \mathbb{Z}, \mathbb{Z}_{\mathrm{tr}}\left(\mathbb{G}_{m}\right)$ is also a Nisnevich sheaf with transfers.

More generally, let $X$ be a smooth scheme, and let $x$ be a $k$-point of $X$ represented by Spec $k \longrightarrow X$. We define the pointed presheaf $\mathbb{Z}_{\operatorname{tr}}(X, x)$ as the cokernel of $x: \mathbb{Z} \longrightarrow$ $\mathbb{Z}_{\mathrm{tr}}(X)$, which defines a splitting of the structure map $\mathbb{Z}_{\operatorname{tr}}(X) \longrightarrow \mathbb{Z}$. By the same reason as above, $\mathbb{Z}_{\operatorname{tr}}(X, x)$ is also a Nisnevich sheaf.

If $\left\{\mathbb{Z}_{\mathrm{tr}}\left(X_{i}, x_{i}\right): i=1, \ldots, n\right\}$ is a collection of pointed schemes, we define their wedge $\operatorname{sum} \bigwedge_{i}^{n} \mathbb{Z}_{\text {tr }}\left(X_{i}, x_{i}\right)$ to be

$$
\operatorname{cok}\left(\bigoplus_{i} \mathbb{Z}_{\mathrm{tr}}\left(X_{1} \times \cdots \times \hat{X}_{i} \times \cdots \times X_{n}\right) \xrightarrow{i d \times \cdots \times x_{i} \times \cdots \times i d} \mathbb{Z}_{\mathrm{tr}}\left(X_{1} \times \cdots \times X_{n}\right)\right)
$$

By induction, $\bigwedge_{i} \mathbb{Z}_{\mathrm{tr}}\left(X_{i}, x_{i}\right)$ is a direct summand of $\mathbb{Z}_{\mathrm{tr}}\left(X_{1} \times \cdots \times X_{n}\right)$ (see [MVW, 2.13]), and defines a Nisnevich sheaf.

In particular, for each nonnegative integer $n$, we can define $\bigwedge_{i=0}^{n} \mathbb{Z}_{\operatorname{tr}}\left(\mathbb{A}^{1}-0,1\right)$, which we view as an object of $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$. In fact, these are geometric motives, i.e., objects in the subcategory $\mathbf{D} \mathbf{M}_{g m}^{\mathrm{eff}},-$. We write this object as $\mathbb{Z}(n)$, which we call the $n$-th motivic complex. It is easy to see that $\mathbb{Z}(n) \otimes^{L} \mathbb{Z}(m) \cong \mathbb{Z}(n+m)$.

Remark 4.3.1. The careful reader may notice that in [MVW], the motivic complex $\mathbb{Z}(n)$ is defined to be $C_{*} \bigwedge_{i}^{n} \mathbb{Z}_{\operatorname{tr}}\left(\mathbb{A}^{1}-0,1\right)$, and not $\bigwedge_{i}^{n} \mathbb{Z}_{\operatorname{tr}}\left(\mathbb{A}^{1}-0,1\right)$ (see [MVW, 3.1]). However, notice that in $\mathbf{D} \mathbf{M}^{\mathrm{eff},-}$, the two definitions of $\mathbb{Z}(n)$ are identified. This is a straightforward consequence of the fact that, for a sheaf with transfers $F$ the cohomological inclusion $F \longrightarrow C_{*} F$ is an $\mathbb{A}^{1}$-weak equivalence (see [MVW, 9.15]).

Remark 4.3.2. Nisnevich motivic cohomology with integer coefficients is defined as

$$
H^{p, q}(X)=\operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},-}\left(\mathbb{Z}_{\mathrm{tr}}(X), \mathbb{Z}(q)[p]\right)
$$

Notice that $\mathbb{Z}(1) \cong \mathcal{O}^{*}[-1]$ ([MVW, 4.1]). Therefore $H^{1,1}(X)=\mathcal{O}^{*}(X)$, and $H^{2,1}=$ $\operatorname{Pic}(X)$. Furthermore, $H^{n, n}(\operatorname{Spec} F)=K_{n}^{M}(F)([\operatorname{MVW}, 5.1])$.

More generally, we have

$$
H^{n, i}(X) \cong C H^{i}(X, 2 i-n)
$$

where $C H^{i}(X, k)$ denote the $k$-th higher Chow group of $X([M V W, 19.1])$.

### 4.4 Cancellation Theorem

We conclude this chapter with an important result, taken from [Voe02, Corollary 4.10]. To simplify notation, for $M$ in $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$, we write $M(1)$ for $M \otimes^{L} \mathbb{Z}(1)$, and $M_{-1}$ for $\underline{\text { RHom }}_{\mathbf{D M}^{\text {eff }},-}(\mathbb{Z}(1), M)$, and write $M(n)$ and $M_{-n}$ for the $n$-th iterations of applying $-\otimes^{L} \mathbb{Z}(1)$ and $\underline{R H o m}_{\mathbf{D M}}{ }^{\text {eff, }}(\mathbb{Z}(1),-)$ respectively to $M$.

As $\mathbb{Z}(n) \otimes^{L} \mathbb{Z}(1)=\mathbb{Z}(n+1)$, the functor given by $M \mapsto M(n)$ is equal to the functor $-\otimes^{L} \mathbb{Z}(n)$. Since right adjoints of the same functor are naturally isomorphic, $M \mapsto M_{-n}$ is naturally isomorphic to $\underline{R H o m}_{\mathbf{D M}^{\text {eff },-}}(\mathbb{Z}(n),-)$. Furthermore, $\mathbb{Z}(1)$ is an object of $\mathbf{D M}_{g m}^{\text {eff,- }}$. Thus, $-\otimes^{L} \mathbb{Z}(1)$ is left adjoint to $\underline{R H o m}_{\mathbf{D M}^{\text {eff }},-}(\mathbb{Z}(1),-)$ by Proposition 4.2.10. More generally, $\mathbb{Z}(n)$ is an object of $\mathbf{D} M_{g m}^{\text {eff,-- }}$ for all positive integer $n$. It follows that $-\otimes^{L} \mathbb{Z}(n)$ is left adjoint to $\underline{R H o m}_{\mathbf{D M}^{\mathrm{eff}},-}(\mathbb{Z}(n),-)$.

Theorem 4.4.1 (Cancellation). For any $M$ and $N$ in $\mathbf{D M}^{\text {eff,--, }}$

$$
\operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},-}(M(1), N(1)) \cong \operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},-}(M, N)
$$

In other words, tensoring with $\mathbb{Z}(1)$ is fully and faithful.
This statement can likewise be interpreted for the category $\mathscr{L}$. For $F^{*}$ and $G^{*}$ bounded above $\mathbb{A}^{1}$-local complexes, by abuse of notation, write $F^{*}(1)$ for $F \otimes_{\mathrm{Nis}}^{\mathbb{L}} C_{*} \mathbb{Z}(1)$. By Theorems 4.4.1 and 4.1.8,

$$
\operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(F^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} C_{*} \mathbb{Z}(1), G^{*} \otimes_{\mathrm{Nis}}^{\mathbb{L}} C_{*} \mathbb{Z}(1)\right) \cong \operatorname{Hom}_{\mathbf{D}^{-} \mathbf{S T}}\left(F^{*}, G^{*}\right)
$$

This is the version of the statement that we will use in subsequent chapters. One important corollary of Theorem 4.4.1 is the following:

Corollary 4.4.2. For each $M$ in $\mathbf{D M}^{\text {eff,-- }}$ and each nonnegative integer $n$, the counit map

$$
M(n)_{-n} \longrightarrow M
$$

is an isomorphism, natural in $M$.

Proof. By Theorem 4.1.8, it suffices to verify the statement for $\mathbb{A}^{1}$-local complexes.
Let $F^{*}$ be the bounded above $\mathbb{A}^{1}$-local complex corresponding to $M$. Notice that by the Cancellation Theorem, reinterpreted for $\mathbb{A}^{1}$-local complexes,

$$
\underline{\operatorname{RHom}}\left(C_{*} \mathbb{Z}(1), C_{*} \mathbb{Z}(1) \otimes_{\text {Nis }}^{\mathbb{L}} F^{*}\right)(U)=\operatorname{RHom}\left(\mathbb{Z}_{\mathrm{tr}}(U), F^{*}\right)=F^{*}(U)
$$

for all $U$ in $\operatorname{Sm}_{k}$. It follows that $\underline{\operatorname{RHom}}\left(C_{*} \mathbb{Z}(1), C_{*} \mathbb{Z}(1) \otimes_{\mathrm{Nis}}^{\mathbb{L}} F^{*}\right) \longrightarrow F^{*}$ is an isomorphism. The corollary now follows by induction on $n$.

## Chapter 5

## Slice Filtration on $\mathrm{DM}^{\text {eff,-- }}$ and DM

In this chapter, we construct a sequence of subcategories on $\mathbf{D M}{ }^{\text {eff,-- }}$ using the tensor and the partial internal hom structure on $\mathbf{D M}{ }^{\text {eff,- }}$ defined in the previous chapter (see Section 4.2). In order to be more precise, we introduce the following notion.

Definition 5.0.1. Let $\mathscr{A}$ be a category. A descending weak filtration of $\mathscr{A}$ is a ( $\mathbb{Z}$ indexed) sequence of subcategories

$$
\mathscr{A} \supseteq \cdots \supseteq \mathscr{A}_{i} \supseteq \mathscr{A}_{i+1} \supseteq \cdots
$$

together with coreflection functors $\varphi_{i}: \mathscr{A} \longrightarrow \mathscr{A}_{i}$ for each $i$ such that $\varphi_{i}$ restricts to the identity on $\mathscr{A}_{i}$. One can similarly define ascending weak filtrations using reflections $\mathscr{A} \longrightarrow \varphi_{n} \mathscr{A}$. We will represent a weak filtration as $\left(\mathscr{A}_{*}, \varphi_{*}\right)$, where $\mathscr{A}_{i}$ are the subcategories and $\varphi_{i}$ are the reflection/coreflections.

We say that a weak filtration $\left(\mathscr{A}_{*}, \varphi_{*}\right)$ is degenerate if all subcategories $\mathscr{A}_{n}$ are equal. If $\mathscr{A}$ has a zero object, then we say that $\left(\mathscr{A}_{*}, \varphi_{*}\right)$ is trivial if each $\mathscr{A}_{n}$ consists of only the zero object.

Remark 5.0.2. An $\mathbb{N}$-indexed descending weak filtration is just a $\mathbb{Z}$-indexed descending weak filtration such that $\mathscr{A}_{j}=\mathscr{A}$ for all $j \leq 0$. Likewise, an $\mathbb{N}$-indexed ascending weak filtration is an ascending weak filtration for which $\mathscr{A}_{j}=\mathscr{A}_{0}$ for all negative $j$.

We show that there are two $\mathbb{N}$-indexed weak filtrations - one ascending, one descending - on $\mathbf{D M}{ }^{\text {eff,-- }}$ defined below in (5.1.1) and (5.1.2). The construction is based on the work of Voevodsky, Huber, and Kahn [HK06]. We then recall the definition of the derived category of motives DM in Definition 5.3.1, and extend the two weak filtrations on $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ to $\mathbb{Z}$-indexed weak filtrations on $\mathbf{D M}$, defined below in (5.3.3)
and (5.3.8). Aside from Lemmas 5.2.1 and 5.2.5 and Propositions 5.2.9 and 5.2.11, the content from the first two sections is taken from [HK06, §1]. The extensions of the filtrations to DM are new.

### 5.1 Slice filtration on $\mathrm{DM}^{\text {eff,- }}$

To simplify notation, following Chapter 4 , we write $M(n)$ for $M \otimes^{L} \mathbb{Z}(n)$, and $M_{-n}$ for $\underline{R H o m}_{\mathbf{D M}^{\text {eff, }}}(\mathbb{Z}(n), M)$. Furthermore, let $L^{n}$ denote the functor $-\otimes^{L} \mathbb{Z}(n)$, and $R^{n}$ denote the functor $\underline{\mathrm{RHom}}_{\mathbf{D M}^{\text {eff,-- }}}(\mathbb{Z}(n),-)$. By convention, define $L^{0}$ and $R^{0}$ to be the identity functor. As we have noted in the paragraph preceding Theorem 4.4.1, ( $L^{n}, R^{n}$ ) form an adjoint pair of triangulated functors for each natural numbers $n$.

We first describe the descending weak filtration on $\mathbf{D M}{ }^{\text {eff,-- }}$. Fix a natural number $n$, let $\mathbf{D} M_{\geq n}^{\text {efff,- }}$ be the full subcategory of objects of the form $M(n)$ for some $M$ in $\mathbf{D} \mathbf{M}^{\mathrm{eff},-}$, and let $\mathbf{D} \mathbf{M}_{<n}^{\mathrm{eff},-}$ be the full subcategory of objects $M$ such that $M_{-n}=0$.

Since $M(n+1)=M(1)(n)$ and $M_{-n}=0$ implies $M_{-(n+1)}=0$, we have the following towers of subcategories:

$$
\begin{align*}
& \mathbf{D M}^{\mathrm{eff},-}=\mathbf{D M}_{\geq 0}^{\mathrm{eff},-} \supseteq \mathbf{D M}_{\geq 1}^{\mathrm{efff},-} \supseteq \mathbf{D M}_{\geq 2}^{\mathrm{eff},-} \supseteq \cdots \supseteq 0  \tag{5.1.1}\\
& 0=\mathbf{D M}_{<0}^{\mathrm{eff},-} \subseteq \mathbf{D M}_{<1}^{\mathrm{eff},-} \subseteq \mathbf{D M}_{<2}^{\mathrm{eff},-} \subseteq \cdots \subseteq \mathbf{D M}^{\mathrm{eff},-} \tag{5.1.2}
\end{align*}
$$

For each $n, L^{n} R^{n}: \mathbf{D M}^{\text {eff,- }} \longrightarrow \mathbf{D M}_{\geq n}^{\text {eff,- }}$ is right adjoint to the inclusion of $\mathbf{D} M_{\geq n}^{\text {eff,- }}$ into $\mathbf{D} M^{\text {eff,- }}$ (see [HK06, 1.1]). Moreover, by Corollary 4.4.2, $R^{n} L^{n} \cong$ id. Since an object $M$ in $\mathbf{D M}_{\geq n}^{\text {eff,-- }}$ is of the form $M^{\prime}(n)$ for some $M^{\prime}$ in $\mathbf{D M}^{\text {eff,-- }}$, and

$$
L^{n} R^{n} M=L^{n} R^{n} M^{\prime}(n) \cong L^{n} M^{\prime}=M
$$

the functor $L^{n} R^{n}$ is naturally isomorphic to the identity on $\mathbf{D M}_{\geq n}^{\text {eff,- }}$.
Definition 5.1.3. Following [HK06], let $\nu^{\geq n}$ denote the triangulated functor $L^{n} R^{n}$. Thus, $\nu^{\geq n} M=M_{-n}(n)$.

Furthermore, for each $M$ in $\mathbf{D} \mathbf{M}^{\text {eff,- }}$, there exists some $M^{\prime}$ in $\mathbf{D M}{ }^{\text {eff,-- }}$ such that there is a distinguished triangle:

$$
\begin{equation*}
\nu^{\geq n} M \longrightarrow M \longrightarrow M^{\prime} \longrightarrow \nu^{\geq n} M[1] . \tag{5.1.4}
\end{equation*}
$$

By [HK06, 1.4(i, ii)], $M^{\prime}$ is uniquely defined up to unique isomorphism, and there is a cohomological functor $\nu^{<n}$ given by $M \mapsto M^{\prime}$, which is the left adjoint to the inclusion of $\mathbf{D} M_{<n}^{\text {eff, }-}$ in $\mathbf{D} \mathbf{M}^{\text {eff,- }}$. If $M$ is in $\mathbf{D M}_{<n}^{\mathrm{eff},-}$, then $\nu^{\geq n} M=M_{-n}(n)=0$. Since (5.1.4) is distinguished, $M \cong \nu^{<n} M$. To show that this isomorphism is natural in $M$, we will prove the stronger result that (5.1.4) is natural in $M$.

Fix a map $f: M \longrightarrow M^{\prime}$ in $\mathbf{D M}^{\text {eff,- }}$. By the naturality of the counit $\epsilon: \nu \geq n \longrightarrow \mathrm{id}$, we have the following commutative square:

Completing the rows of the square into distinguished triangles, we have the following commutative diagram

Since $\nu^{<n}$ is left adjoint to the inclusion of $\mathbf{D} \mathbf{M}_{<n}^{\text {eff,- }}$ into $\mathbf{D M}{ }^{\text {eff,- }}$,

$$
\operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},-}\left(M, \nu^{<n} M^{\prime}\right) \cong \operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},-}\left(\nu^{<n} M, \nu^{<n} M^{\prime}\right)
$$

Hence, the induced map from $\nu^{<n} M \longrightarrow \nu^{<n} M^{\prime}$ (the dotted arrow in the diagram above) is $\nu^{<n} f$. We summarize the main results of the above discussion in the following proposition:

Proposition 5.1.5. The tower of subcategories in (5.1.1) defines a descending weak filtration of $\mathbf{D M}^{\text {eff,-- }}$, where the coreflection functors

$$
\nu^{\geq n}: \mathbf{D M}^{\text {eff,- }} \longrightarrow \mathbf{D M}_{\geq n}^{\text {eff, }}
$$

are defined by $M \mapsto M_{-n}(n)$.
Furthermore, the tower in (5.1.2) defines an ascending weak filtration of $\mathbf{D M}{ }^{\text {eff,-- }}$, with reflection functors

$$
\nu^{<n}: \mathbf{D M}^{\mathrm{eff},-} \longrightarrow \mathbf{D M}_{<n}^{\mathrm{eff},-},
$$

defined by sending $M$ to $M^{\prime}$ in the triangle given in (5.1.4).

We call the pair of weak filtrations associated with the towers in (5.1.1) and (5.1.2) the slice filtration on $\mathbf{D M}{ }^{\mathrm{eff},-}$.

Notice that, by replacing $M$ by $\nu^{\geq n} M$ in (5.1.4), we get distinguished triangles for all positive integers $m$ and $n$, all of which are natural in $M$ :

$$
\begin{equation*}
\nu^{\geq n} \nu^{\geq m} M \longrightarrow \nu^{\geq m} M \longrightarrow \nu^{<n} \nu^{\geq m} M \longrightarrow \nu^{\geq n} \nu^{\geq m} M[1] . \tag{5.1.6}
\end{equation*}
$$

### 5.2 Fundamental invariants of the slice filtration

In this section, following [HK06, 1.4 (iv, v)], we define the slice and fundamental invariant functors associated to the slice filtration on $\mathbf{D M}{ }^{\text {eff,-- }}$. Before we do so, we will show that the functors $\nu^{\geq n}$ and $\nu^{<n}$ satisfy a number of properties described in Proposition 5.2.11. Lemmas 5.2.1 and 5.2.5 and Propositions 5.2.9 and 5.2.11 are new.

We first digress to discuss two results from category theory. For the following, let $L$ and $R$ be a pair of adjoint endofunctors on $\mathscr{C}$, and suppose that the unit $\eta:$ id $\longrightarrow$ $R L$ is a natural isomorphism. Write $L^{n}$ and $R^{n}$ for the $n$-th iteration of $L$ and $R$ respectively. Since $L$ and $R$ are adjoint functors, so are $L^{n}$ and $R^{n}$. Write $\epsilon^{n}$ for the counit $L^{n} R^{n} \longrightarrow \mathrm{id}$ and $\eta^{n}$ for the unit id $\longrightarrow R^{n} L^{n}$. In this case, $\eta^{n}$ is also a natural isomorphism for each positive integer $n$.

Lemma 5.2.1. For each positive integer $n$, the natural isomorphism $\left(L^{n+1} R^{n} \eta\right)^{-1}$ : $L^{n+1} R^{n+1} L \longrightarrow L\left(L^{n} R^{n}\right)$ fits into the following commutative diagram of natural transformations:

Dually, the natural isomorphism $\eta L^{n} R^{n+1}: L^{n} R^{n} R \longrightarrow R\left(L^{n+1} R^{n+1}\right)$ fits into the following commutative diagram of natural transformations:

Proof. We first show that (5.2.2) is commutative. To do so, we proceed by induction on $n$. For the case $n=0$, by the counit-unit adjunction, the following composition is the identity transformation:

$$
L \xrightarrow{L \eta} L R L \xrightarrow{\epsilon L} L .
$$

Therefore, $\epsilon L=L\left(\eta^{-1}\right)$, and the following diagram commutes:

Now assume that for some integer $n$, the following diagram is commutative:

Write $\epsilon^{\prime}$ for the natural transformation $L^{n} \epsilon R^{n}: L^{n} R^{n} \longrightarrow L^{n-1} R^{n-1}$. Applying the naturality of $\epsilon^{\prime}$ to the natural isomorphism $\eta^{-1}: R L \longrightarrow \mathrm{id}$, we have the following commutative diagram

Now apply $L$ to the above, we have

which fits together with (5.2.4) to give the following commutative diagram:

Notice that $\epsilon^{n} \circ L \epsilon^{\prime} R=\eta^{n+1}$ and $\epsilon^{n-1} \circ \eta^{\prime}=\epsilon^{n}$. Therefore, in the diagram above, the composition of the two maps in the top row is precisely $\epsilon^{n+1} L$ and the composition
of in the bottom row is precisely $L \epsilon^{n}$. By induction, the commutativity of (5.2.2) is established. The commutativity of (5.2.3) follows by similar arguments.

Lemma 5.2.5. For all positive integers $n$ and $m$, there exists a natural isomorphism $\tau: L^{n} R^{n} L^{m} R^{m} \longrightarrow L^{m} R^{m} L^{n} R^{n}$ such that the following is a commutative diagram of natural transformations:

Proof. We first consider the case $m \leq n$. By the counit-unit adjunction, the composition

$$
R^{m} \xrightarrow{\eta^{m} R^{m}} R^{m} L^{m} R^{m} \xrightarrow{R^{m} \epsilon^{m}} R^{m}
$$

is the identity transformation. Applying $L^{n} R^{n-m}$ to the above, we obtain the following commutative square:

Similarly, by the unit-counit adjunction, the compositions

$$
L^{m} \xrightarrow{L^{m} \eta^{m}} L^{m} R^{m} L^{m} \xrightarrow{\epsilon^{m} L^{m}} L^{m}
$$

is also the identity transformation. Applying the above to $L^{n-m} R^{n}$, we obtain the following commutative square:

Combining these squares, and setting

$$
\tau \stackrel{\text { def }}{=}\left(L^{m} \eta^{n} L^{n-m} R^{n}\right) \circ\left(L^{n} R^{n-m} \eta^{m} R^{m}\right)^{-1},
$$

we obtain the commuting square (5.2.6) for $n \geq m$.

For the case $n<m$, iterating on the results of Lemma 5.2.1, we have the following commutative diagrams:

and

Applying (5.2.8) to $R^{n}$ and $L^{n}$ to (5.2.7), the resulting diagrams fit together to give

By setting

$$
\tau \stackrel{\text { def }}{=}\left(L^{n} \eta^{n} L^{m-n} R^{m-n}\right)^{-1} \circ L^{m} R^{m-n} \eta^{n} R^{n},
$$

we see that (5.2.6) is commutative, and the lemma is established.
Applying Lemma 5.2.5 to the pair of adjoint functors $M \mapsto M(n)$ and $M \mapsto M_{-n}$ on $\mathbf{D M}{ }^{\text {eff,- }}$, we obtain the following proposition:

Proposition 5.2.9. There is a natural isomorphism $\nu^{\geq n} \nu^{\geq m} \xrightarrow{\tau} \nu^{\geq m} \nu^{\geq n}$ fitting into the following commutative diagram of natural transformations:

where $\epsilon^{m}: \nu^{\geq m} \longrightarrow \mathrm{id}$ is the unit. Furthermore, $\nu^{\geq n} \epsilon^{m}$ and $\epsilon^{m} \nu^{\geq n}$ are natural isomorphisms.

Proposition 5.2.11. For all nonnegative integers $m$, $n$, such that $m \leq n$, and for all $M$ in $\mathbf{D M}{ }^{\text {eff,-- }}$, there exists the following natural isomorphisms:

1. $\nu^{\geq m_{\nu}<n} \cong \nu^{<n} \nu^{\geq m}$.
2. $\nu^{\geq n} \nu^{<m}=\nu^{<m} \nu^{\geq n}=0$.
3. $\nu^{<m} \nu^{<n} \cong \nu^{<n} \nu^{<m} \cong \nu^{<m}$.
4. $\left(\nu^{\geq n} M\right)(k)=\nu^{\geq n+k} M(k)$ for all positive integers $k$.

Proof. For part (1), apply the commutative diagram of functors (5.2.10) in Proposition 5.2 .9 to an object $M$ of $\mathbf{D M}{ }^{\text {eff,- }}$, and extend the rows to triangles. We obtain the following commutative diagram:

By the Five Lemma ([Wei94, 10.2.2]), we have that

$$
\nu^{\geq m} \nu^{<n} M \cong \nu^{<n} \nu^{\geq m} M .
$$

Since the rows are functorial in $M$ and the isomorphism $\nu^{\geq n} \nu^{\geq m} M \longrightarrow \nu^{\geq m} \nu^{\geq n} M$ is natural, for a given map $f: M \longrightarrow M^{\prime}$, the induced maps $\nu^{<n} \nu^{\geq m}(f)$ and $\nu^{\geq m} \nu^{<n}(f)$ fit into the following commutative square:

Therefore, $\nu^{\geq m_{\nu}}{ }^{<n}$ is naturally isomorphic to $\nu^{<n} \nu^{\geq m}$.
Since $\left(\nu^{<m}\right)_{-n}=0$, it is clear that $\nu^{\geq n} \nu^{<m}=0$. On the other hand, by Proposition 5.2.9, $\nu^{\geq m} \nu^{\geq n}=\nu^{\geq n}$. From the following functorial distinguished triangle

$$
\nu^{\geq m} \nu^{\geq n} \longrightarrow \nu^{\geq n} \longrightarrow \nu^{<m} \nu^{\geq n} \longrightarrow \nu^{\geq m} \nu^{\geq n}[1]
$$

it follows that $\nu^{<n} \nu^{\geq m}=0$, which proves (2).
For (3), apply the slice triangle (5.1.4) to $\nu^{<n} M$ to obtain:

$$
\nu^{\geq m} \nu^{<n} M \longrightarrow \nu^{<n} M \longrightarrow \nu^{<m} \nu^{<n} M \longrightarrow \nu^{\geq m} \nu^{<n} M[1] .
$$

Applying $\nu^{<n}$ to the slice triangle of $M$ gives:

$$
\nu^{<n} \nu^{\geq m} M \longrightarrow \nu^{<n} M \longrightarrow \nu^{<n} \nu^{<m} M \longrightarrow \nu^{<n} \nu^{\geq m} M[1],
$$

and by part (2), there exists a natural isomorphism $\nu^{\geq m} \nu^{<n} M \longrightarrow \nu^{<n} \nu^{\geq m}$ which fits into the following commutative diagram:

The fact that $\nu^{<n} \nu^{<m} M \cong \nu^{<m} \nu^{<n} M$ follows from the Five Lemma. Naturality in $M$ now follows from part (1).

For part (4), the case $k=1$ is established in [HK06, 1.4(v)]. The general case follows by induction on $k$.

Setting $m=n-1$ in (5.1.6), we obtain the following functorial distinguished triangle:

$$
\begin{equation*}
\nu^{\geq n} \longrightarrow \nu^{\geq n-1} \longrightarrow \nu^{<n} \nu^{\geq n-1} \longrightarrow \nu^{\geq n}[1] . \tag{5.2.12}
\end{equation*}
$$

Definition 5.2.13. For $M$ in $\mathbf{D} M^{\text {eff,- }}$ and positive integer $n$, we say $\nu^{<n+1} \nu^{\geq n} M$ is the $n$-th slice of $M$, written as $\nu^{n} M$. Since $\nu^{<n}$ and $\nu^{\geq n}$ are triangulated functors, so is $\nu^{n}$. We define the 0 -th slice functor to be $\nu^{<0}$.

By Proposition 5.2.11(1), $\nu^{n} \cong \nu^{\geq n} \nu^{<n-1}$. In particular, the image of $\nu^{n}$ is in $\mathbf{D M}_{\geq n}^{\text {eff, }-}$. That is, for each $M$ in $\mathbf{D M}^{\text {eff,- }}$, there exists some $M^{\prime}$ such that $\nu^{n} M \cong$ $M^{\prime}(n)$. Setting $M^{\prime \prime} \stackrel{\text { def }}{=} M^{\prime}[-2 n]$, we obtain the following proposition:

Proposition 5.2.14 ([HK06], 1.4(v)). For each n and $M, \nu^{n} M=M^{\prime \prime}(n)[2 n]$ for some unique $M^{\prime \prime}$ in $\mathbf{D M}^{\mathrm{eff},-}$. The object $M^{\prime \prime}$ is defined up to unique isomorphism.

Definition 5.2.15. Following loc. cit., we call $M^{\prime \prime}$ in Proposition 5.2.14 the $n$-th fundamental invariant of $M$, which we write as $c_{n} M$. For each positive $n, c_{n}$ is an endofunctor on $\mathbf{D M}{ }^{\text {eff,-- }}$.

Example 5.2.16. It is clear that $\mathbb{Z}(n)$ is its own $n$-th slice. Furthermore, since $M\left(\mathbb{P}^{n}\right)=\oplus_{i=0}^{n} \mathbb{Z}(n)[2 n]$ (see [MVW, 15.5]), it is easy to verify that

$$
\nu^{<k} M\left(\mathbb{P}^{n}\right)= \begin{cases}M\left(\mathbb{P}^{k}\right) & \text { if } k \leq n \\ M\left(\mathbb{P}^{n}\right) & \text { otherwise }\end{cases}
$$

and

$$
\nu^{\geq k} M\left(\mathbb{P}^{k}\right)= \begin{cases}M\left(\mathbb{P}^{n-k}\right)(k)[2 k] & \text { if } k \leq n \\ 0 & \text { otherwise }\end{cases}
$$

Therefore, $\nu^{k} M\left(\mathbb{P}^{n}\right)=\mathbb{Z}(k)[2 k]$, and the $k$-th fundamental invariant of $M\left(\mathbb{P}^{n}\right)$ is $c_{k} M\left(\mathbb{P}^{n}\right)=\mathbb{Z}$, for $k=0,1, \ldots, n$.

### 5.3 Slice filtration on DM

In this section, we will extend the slice filtration on $\mathbf{D M}{ }^{\text {eff,- }}$ to $\mathbb{Z}$-indexed filtrations on DM. Recall from [MVW, 14.2] the following definition of the category DM.

Definition 5.3.1. Let $\mathbf{D M}$ be the category obtained from $\mathbf{D M}{ }^{\text {eff,- }}$ by inverting the operation $M \mapsto M(1)$. That is, the objects of $\mathbf{D M}$ are pairs $(M, n)$, where $M$ is an object of $\mathbf{D} \mathbf{M}^{\text {eff,- }}$, and $n$ is any integer, such that $(M(1), n) \cong(M, n+1)$; the set of morphism between $(M, n)$ and ( $M^{\prime}, n^{\prime}$ ) is

$$
\underset{k}{\lim } \operatorname{Hom}_{\mathbf{D M}^{\text {eff }},-}\left(M(k+n), M^{\prime}\left(k+n^{\prime}\right)\right) .
$$

as $k$ ranges over all integer values for which $k+n$ and $k+n^{\prime}$ are positive. We write $\operatorname{Hom}_{\mathbf{D M}}\left((M, n),\left(M^{\prime}, n^{\prime}\right)\right)$ for the hom set of $(M, n)$ and $\left(M^{\prime}, n^{\prime}\right)$.

By induction, we have that $(M, n) \cong\left(M \otimes^{L} \mathbb{Z}(n), 0\right)$, for any positive integer $n$ and all $M$ in $\mathbf{D} M^{\text {eff,- }}$. In particular, if $(M, n) \cong\left(M^{\prime}, n^{\prime}\right)$ for $n \geq n^{\prime}$, then $M \cong M^{\prime}\left(n-n^{\prime}\right)$.

Furthermore, by the Cancellation Theorem (Theorem 4.4.1),

$$
\operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},-}^{\mathrm{ef}}\left(M, M^{\prime}\right)=\operatorname{Hom}_{\mathbf{D M}^{\text {eff }},-}\left(M(n), M^{\prime}(n)\right)
$$

for all positive integers. Therefore, the colimit in the definition of $\boldsymbol{H o m}_{\mathbf{D M}}$ is a finite limit. That is, it suffices to take $k>|n|+\left|n^{\prime}\right|$, say.

By the Cancellation Theorem 4.4.1, the localization functor $\Sigma^{\infty}: \mathbf{D M}^{\text {eff,-- }} \longrightarrow \mathbf{D M}$, given by sending $M$ in $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$ to $(M, 0)$ is fully faithful. Therefore, we can identify $\mathbf{D M}^{\text {eff,-- }}$ as a full subcategory of $\mathbf{D M}$.

We will now give a description of the subcategories in the slice filtration on DM. Each subcategory in the slice filtration will be full, and we describe only the objects in these subcategories.

Definition 5.3.2. For each integer $k$, let the objects of $\mathbf{D M}_{\geq k}$ consist of objects ( $M, n$ ) for which $n \geq k$. As defined, $\mathbf{D M}_{\geq n+1} \subseteq \mathbf{D M}_{\geq n}$ and therefore, we have the following tower of subcategories:

$$
\begin{equation*}
\mathbf{D M} \supseteq \cdots \mathbf{D M}_{\geq-1} \supseteq \mathbf{D M}_{\geq 0} \supseteq \mathbf{D M}_{\geq 1} \supseteq \cdots \tag{5.3.3}
\end{equation*}
$$

Notice that for $n \geq 0,(M, n) \cong(M(n), 0)$. Therefore, if $M \cong M^{\prime}(n)$ for some $M^{\prime}$ in $\mathbf{D M}^{\text {efff,- }},(M, 0) \cong\left(M^{\prime}, n\right)$ in $\mathbf{D M}$. Conversely, if $(M, 0)$ is in $\mathbf{D M} \geq_{n}$, then $(M, 0) \cong\left(M^{\prime}, n\right)$ for some $M^{\prime}$ in $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$. Hence, $M \cong M^{\prime}(n)$ in $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$. It follows that the image of $\mathbf{D} \mathbf{M}_{\geq n}^{\text {eff,- }}$ under $\Sigma^{\infty}$ coincides with $\mathbf{D M}_{\geq n}$, when $n \geq 0$. In Definition 5.3.4, we define a way to associate every object ( $M, n$ ) in DM with an object $\nu^{\geq 0}(M, n)$ in $\mathbf{D M}_{\geq 0}$, and in Proposition 5.3.6, we show that $\nu^{\geq 0}$ is right adjoint to $\Sigma^{\infty}$. Therefore, we can realize $\mathbf{D M}{ }^{\text {eff,- }}$ as a coreflective subcategory of $\mathbf{D M}$.

To show that this tower of subcategories constitutes a weak filtration of DM, we must construct an extension of the functors $\nu^{\geq k}$ of Definition 5.1.3. By convention, for all $M$ in $\mathbf{D} M^{\text {eff,- }}$, define $\nu^{\geq n} M$ to be $M$ for all $n \leq 0$.

Definition 5.3.4. For any integer $k$ and a given object $(M, n)$ in DM, we set

$$
\nu^{\geq k}(M, n) \stackrel{\text { def }}{=}\left(\nu^{\geq k-n} M, n\right) .
$$

This definition preserves isomorphisms. Indeed, if $(M, n) \cong\left(M^{\prime}, n^{\prime}\right)$ for some integer $n^{\prime}$ less than $n$, say, then $M\left(n-n^{\prime}\right)=M^{\prime}$, and $\nu^{\geq k-n^{\prime}} M^{\prime} \cong \nu^{\geq k-n} M\left(n-n^{\prime}\right)$ by (4) of Proposition 5.2.11. Hence, $\left(\nu^{\geq k-n^{\prime}} M^{\prime}, n^{\prime}\right) \cong\left(\nu^{\geq k-n} M, n\right)$.

We want to show that the $\nu^{\geq k}$ are triangulated functors from $\mathbf{D M}$ to $\mathbf{D M}_{\geq k}$ that make $\left(\mathbf{D M}_{\geq k}, \nu^{\geq k}\right)$ into a weak filtration. We will verify this claim in the Proposition 5.3.6. Let us first prove the following lemma:

Lemma 5.3.5. If $\left(M_{1}, n\right) \longrightarrow\left(M_{2}, n\right) \longrightarrow\left(M_{3}, n_{3}\right) \longrightarrow\left(M_{1}, n\right)[1]$ is a distinguished triangle in $\mathbf{D M}$, then there exists some $M$ such that $(M, n) \cong\left(M_{3}, n_{3}\right)$.

Proof. Let $\varphi$ denote the map from $\left(M_{1}, n\right)$ to $\left(M_{2}, n\right)$. Then $\varphi$ is identified with some $\operatorname{map} \varphi^{\prime}: M_{1} \longrightarrow M_{2}$ in $\mathbf{D M}^{\text {eff,-- }}$. Complete $\varphi^{\prime}$ to a triangle:

$$
M_{1} \longrightarrow M_{2} \longrightarrow M \longrightarrow M_{1}[1] .
$$

Then, we have

The claim now follows from the Five Lemma.

Proposition 5.3.6. Let $k$ be an arbitrary integer.

1. $(M, n) \mapsto \nu^{\geq k}(M, n)$ defines a triangulated functor.
2. $\nu^{\geq k}$ is a right adjoint to the inclusion of $\mathbf{D M}_{\geq k}$ into $\mathbf{D M}$.
3. the restriction of $\nu^{\geq k}$ to $\mathbf{D M}_{\geq k}$ is naturally isomorphic to the identity.

Proof. If $k \leq n$, then $\nu^{\geq k}(M, n)=(M, n)$, and by definition $(M, n)$ is an object of $\mathbf{D M}_{\geq k}$. On the other hand, if $k>n$, then as defined, $\nu^{\geq k}(M, n)=\left(\nu^{\geq k-n} M, n\right)$. By [HK06, 1.1], $\nu^{\geq k-n} M$ is in $\mathbf{D M}_{\geq k-n}^{\text {eff, }}$. Hence, $M \cong M^{\prime}(k-n)$. Therefore, $\nu^{\geq k}(M, n) \cong$ $\left(M^{\prime}(k-n), n\right) \cong\left(M^{\prime}, k\right)$. This shows that $\nu^{\geq k}(M, n)$ is always an object of $\mathbf{D M}_{\geq k}$.

Consider a map $f:(M, n) \longrightarrow\left(M^{\prime}, n^{\prime}\right)$. Since we have already shown that $\nu^{\geq k}$ preserves isomorphisms, by replacing either $(M, n)$ or $\left(M^{\prime}, n^{\prime}\right)$ by an isomorphic object, we may assume that $n=n^{\prime}$, and $f$ comes from a map $g: M \longrightarrow M^{\prime}$ in $\mathbf{D M}^{\mathrm{eff},-}$. Define $\nu^{\geq k}(f)$ to be the map given by $\nu^{\geq k-n} g$ in $\mathbf{D M}^{\text {eff,- }}$. This definition preserves the identity map, isomorphisms, and composition. It follows that $\nu^{\geq k}$ is a functor on $\mathbf{D M}$ whose image lies in $\mathbf{D M}_{\geq k}$.

Given a triangle,

$$
\left(M^{\prime}, n^{\prime}\right) \longrightarrow(M, n) \longrightarrow\left(M^{\prime \prime}, n^{\prime \prime}\right) \longrightarrow\left(M^{\prime}, n^{\prime}\right)[1]
$$

we may assume without loss of generality that $n=n^{\prime}=n^{\prime \prime}$, and that this distinguished triangle comes from the distinguished triangle in $\mathbf{D M}{ }^{\text {eff,-- }}$ :

$$
M^{\prime} \longrightarrow M \longrightarrow M^{\prime \prime} \longrightarrow M^{\prime}[1]
$$

Since $\nu^{\geq k-n}$ is a triangulated functor on $\mathbf{D M}{ }^{\text {eff,-- }}$ (see Definition 5.1.3), it follows that

$$
\nu^{\geq k-n} M^{\prime} \longrightarrow \nu^{\geq k-n} M \longrightarrow \nu^{\geq k-n} M^{\prime \prime} \longrightarrow \nu^{\geq k-n} M^{\prime}[1]
$$

is a distinguished triangle in $\mathbf{D} \mathbf{M}^{\text {eff,- }}$. Thus, we have the following distinguished triangle in $\mathbf{D M}$ :

$$
\nu^{\geq k}\left(M^{\prime}, n\right) \longrightarrow \nu^{\geq k}(M, n) \longrightarrow \nu^{\geq k}\left(M^{\prime \prime}, n\right) \longrightarrow \nu^{\geq k}\left(M^{\prime}, n\right)[1] .
$$

Therefore, $\nu^{\geq k}$ is a triangulated functor, which proves part (1) of the proposition.
For part (2), let ( $M, n$ ) be an object of $\mathbf{D M}$, and ( $M^{\prime}, n^{\prime}$ ) be an object of $\mathbf{D M}_{\geq k}$. By replacing ( $M^{\prime}, n^{\prime}$ ) with an isomorphic object, we may assume that $n^{\prime}=k$. In the case $n>k$, notice that $\nu^{\geq k}(M, n)=(M, n)$, and the adjunction relation is trivially satisfied. Otherwise, for some suitably large integer $l$, we have the following equality:

$$
\operatorname{Hom}_{\mathbf{D M}}\left(\left(M^{\prime}, k\right),(M, n)\right)=\operatorname{Hom}_{\mathbf{D M}^{\text {eff }},-}\left(M^{\prime}(l+k), M(l+n)\right) .
$$

Since $M^{\prime}(l+k) \in \mathbf{D M}_{\geq k+l}^{\text {eff,- }}$ and $\nu^{\geq k+l}$ is right adjoint to the inclusion of $\mathbf{D M}{ }_{\geq l+k}^{\text {eff,- }}$ into $\mathbf{D M}^{\text {eff,- }}$,

$$
\operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},--}\left(M^{\prime}(l+k), M(l+n)\right) \cong \operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff},-}}\left(M^{\prime}(l+k), \nu^{\geq k+l} M(l+n)\right) .
$$

Notice that by Proposition 5.2.11(4), $\nu^{\geq k+l} M(n+l) \cong\left(\nu^{\geq k-n} M\right)(n+l)$. Therefore,

$$
\begin{aligned}
\operatorname{Hom}_{\mathbf{D M}}\left(\left(M^{\prime}, k\right),(M, n)\right) & \cong \operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},--}\left(M^{\prime}(l+k),\left(\nu^{\geq k-n} M\right)(l+n)\right) \\
& \cong \operatorname{Hom}_{\mathbf{D M}^{\mathrm{eff}},-}\left(\left(M^{\prime}, k\right), \nu^{\geq k}(M, n)\right) .
\end{aligned}
$$

Since the isomorphism is functorial in both $(M, n)$ and $\left(M^{\prime}, k\right)$, it follows that $\nu^{\geq k}$ is right adjoint to the inclusion of $\mathbf{D M}_{\geq k}$ into $\mathbf{D M}$.

For part (3), if $(M, n)$ is an object of $\mathbf{D M}_{\geq k}$, then $(M, n) \cong\left(M^{\prime}, k\right)$ for some $M^{\prime}$. Furthermore, as defined, $\nu^{\geq k}\left(M^{\prime}, k\right)=\left(M^{\prime}, k\right)$. As this isomorphism is natural in ( $M, n$ ), we have just established part (3).

Next, we construct the ascending weak filtration on DM.
Definition 5.3.7. Let $\mathbf{D M}{ }_{<k}$ to be the full subcategory of objects ( $M, n$ ) in $\mathbf{D M}$ for which $\nu^{\geq k}(M, n)=0$. Since $\nu^{\geq k}(M, n)=\left(\nu^{\geq k-n} M, n\right)=0$ implies that $\nu^{\geq k+1}(M, n)=$ $\left(\nu^{\geq k+1-n} M, n\right)=0, \mathbf{D M}_{<k+1}$ is a subcategory of $\mathbf{D M}_{<k}$, and we obtain the following tower of subcategories:

$$
\begin{equation*}
0 \subseteq \cdots \subseteq \mathbf{D M}_{<0} \subseteq \mathbf{D M}_{<1} \subseteq \mathbf{D M}_{<2} \subseteq \cdots \subseteq \mathbf{D M} \tag{5.3.8}
\end{equation*}
$$

As expected, the tower also defines a filtration of $\mathbf{D M}$, and to show this, we will define the reflection functors $\nu^{<k}: \mathbf{D M} \longrightarrow \mathbf{D M}_{<k}$. These reflection functors will come from extending the endofunctor $\nu^{<k}$ of $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ to endofunctors on $\mathbf{D M}$. By convention, for a nonpositive integer $k$, let us define the endofunctor $\nu^{<k}$ on $\mathbf{D M}^{\text {eff,- }}$ to be 0 . For $(M, n)$ in DM, we have the following triangle

$$
\begin{equation*}
\nu^{\geq k}(M, n) \longrightarrow(M, n) \longrightarrow\left(M^{\prime}, n^{\prime}\right) \longrightarrow \nu^{\geq k}(M, n)[1] . \tag{5.3.9}
\end{equation*}
$$

Lemma 5.3.10. For each integer $k$, the object $\left(M^{\prime}, n^{\prime}\right)$ in (5.3.9) is defined up to unique isomorphism. In particular, $\left(M^{\prime}, n^{\prime}\right)$ is uniquely isomorphic to $\left(\nu^{<k-n} M, n\right)$.

Proof. By definition, $\nu^{\geq k}(M, n)=\left(\nu^{\geq k-n} M, n\right)$. By Lemma 5.3 .5 we may assume $n^{\prime}=n$, and $\nu^{\geq k-n} M \longrightarrow M \longrightarrow M^{\prime} \longrightarrow \nu^{\geq k-n} M[1]$ is a distinguished triangle in $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$. Since $M^{\prime}$ is uniquely defined up to unique isomorphism (see [HK06, 1.3(i)]), $M^{\prime} \cong \nu^{<k-n} M$, and $\left(M^{\prime}, n^{\prime}\right) \cong\left(\nu^{<k-n} M, n\right)$ as claimed.

Recall the convention that for $k<0, \nu^{<k}=0$ as an endofunctor on $\mathbf{D M}{ }^{\text {eff,-- }}$. We now define the extension of $\nu^{<k}$ as endofunctors on DM. As we will see in Proposition 5.3.12, the functors $\nu^{<k}$ are the reflection from $\mathbf{D M}$ to $k_{<*} \mathbf{D M}$.

Definition 5.3.11. For any integer $k$ and a given object ( $M, n$ ) in DM, we set

$$
\nu^{<k}(M, n) \stackrel{\text { def }}{=}\left(\nu^{<k-n} M, n\right) .
$$

Copying the proof of [HK06, 1.3], $(M, n) \mapsto \nu^{<k}(M, n)$ defines a triangulated functor on DM.

The arguments of [HK06, 1.3] can be adapted for $\nu^{<k}$ to show the following proposition.

Proposition 5.3.12. For each integer $k$,

1. $\nu^{<k}$ is a triangulated functor
2. the image of $\nu^{<k}$ is $\mathbf{D M}_{<k}$ and $\nu^{<k}$ defines a left adjoint to the inclusion of $\mathbf{D M}_{<k}$ into $\mathbf{D M}$.
3. the restriction of $\nu^{<k}$ to $\mathbf{D M}_{<k}$ is naturally isomorphic to the identity.
4. If $k>0$, the restriction of $\nu^{<k}$ to $\mathbf{D} \mathbf{M}^{\mathrm{eff},-}$ is the functor $\nu^{<k}$ of Proposition 5.1.5.

It follows that the towers of subcategories given in (5.3.3) and (5.3.8) respectively define a descending and an ascending filtration on DM.

### 5.4 Extending the fundamental invariants

We can also extend the definition of the fundamental invariants $c_{k}$ to negative integers $k$. Notice that for each $(M, n)$ in $\mathbf{D M}$, and each integer $k$, we have the slice triangle:

$$
\nu^{\geq k+1}(M, n) \longrightarrow \nu^{\geq k}(M, n) \longrightarrow \nu^{<k+1} \nu^{\geq k}(M, n) \longrightarrow \nu^{\geq k+1}(M, n)[1] .
$$

Definition 5.4.1. Let us define $\nu^{k}$ to be $\nu^{<k+1} \nu^{\geq k}$. We call this functor the $k$-th slice on DM. Since both $\nu^{<k+1}$ and $\nu^{\geq k}$ are triangulated functors, so is $\nu^{k}$.

By arguments similar to those in the proof of Proposition 5.2.14, we have that $\nu^{k}(M, n) \cong\left(M^{\prime \prime}[2 k], k\right)$ for some $M^{\prime \prime}$ in $\mathbf{D M}{ }^{\mathrm{eff},-}$, which is unique up to unique isomorphism. We define the $k$-th fundamental invariant of $(M, n)$ to be

$$
c_{k}(M, n) \stackrel{\text { def }}{=} M^{\prime \prime}
$$

For each integer $k, c_{k}$ is a functor from $\mathbf{D M}$ to $\mathbf{D} \mathbf{M}^{\text {eff,- }}$.
Notice that for $k \geq 0$, if $(M, n)$ is in $\mathbf{D M}{ }^{\text {eff,- }}$, the definition of $\nu^{k}$ recovers the $k$-th slice functor in Definition 5.2.13 by Proposition 5.3.12. Similarly, $c_{k}$ is an extension of the $k$-th fundamental invariant on $\mathbf{D M}{ }^{\text {eff,- }}$.

We conclude this section by discussing the relationship between the tensor structure on $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ and $\mathbf{D M}$ and their respective slice filtrations. First, let us define a tensor product on DM. By abuse of notation, we will also represent this tensor product by $\otimes^{L}$.

Definition 5.4.2. Following [MVW, 8A], for objects ( $M, n$ ), ( $M^{\prime}, n^{\prime}$ ) in DM, we define $(M, n) \otimes^{L}\left(M^{\prime}, n^{\prime}\right)$ to be $\left(M \otimes^{L} M^{\prime}, n+n^{\prime}\right)$. As shown in [MVW, 15.8], the cyclic permutation of $\mathbb{Z}(1)^{\otimes 3}$ is the identity in $\mathbf{D M}{ }^{\text {eff,- }}$. By [MVW, 8A.12] the triangulated category $\mathbf{D M}$ together with $\otimes^{L}$ defines $\left(\mathbf{D M}, \otimes^{L}\right)$ is an additive symmetric monoidal triangulated category.

Let us first consider the following result, which relate the slice filtration to the tensor product on $\mathbf{D M}^{\text {eff,- }}$.

Proposition 5.4.3 ([HK06] 1.6). For nonnegative integers $n, n^{\prime}$, there exists a unique natural isomorphism $\eta: \nu^{\geq n} \otimes^{L} \nu^{\geq n^{\prime}} \longrightarrow \nu^{\geq n+n^{\prime}}\left(-\otimes^{L}-\right)$ compatible with the tensor structure on $\mathbf{D M}^{\mathrm{eff},-}$. That is, we have the following commutative square for each $M$ and $M^{\prime}$ in $\mathbf{D M}^{\text {eff,- }}$ :

We can extend this result to DM. The following is a straightforward consequence of Proposition 5.4.3.

Corollary 5.4.4. For all integers $n, n^{\prime}$, there exists a unique natural transformation of bifunctors on $\nu^{\geq n} \otimes^{L} \nu^{\geq n^{\prime}} \longrightarrow \nu^{\geq n+n^{\prime}}\left(-\otimes^{L}-\right)$ compatible with the tensor structure of DM.

A corollary of Proposition 5.4.3 applies to the tensor structure on the slices (and similarly, on the fundamental invariants) of the slice filtration.

Corollary 5.4.5. For all integers nonnegative $n, n^{\prime}$, there exists unique natural transformations of bifunctors $\nu^{n} \otimes^{L} \nu^{n^{\prime}} \longrightarrow \nu^{n+n^{\prime}}\left(-\otimes^{L}-\right)$ and $c_{n} \otimes^{L} c_{n^{\prime}} \longrightarrow c_{n+n^{\prime}}\left(-\otimes^{L}-\right)$ compatible with the tensor structure on $\mathbf{D M}^{\text {eff,-- }}$.

The natural transformations can be extended to natural transformations on the slice structure on DM: we have natural transformations $\nu^{n} \otimes^{L} \nu^{n^{\prime}} \longrightarrow \nu^{n+n^{\prime}}\left(-\otimes^{L}-\right)$ and $c_{n} \otimes^{L} c_{n^{\prime}} \longrightarrow c_{n+n^{\prime}}\left(-\otimes^{L}-\right)$ compatible with the tensor structure on $\mathbf{D M}$.

Proof. The existence of natural transformations $\nu^{n} \otimes^{L} \nu^{n^{\prime}} \longrightarrow \nu^{n+n^{\prime}}\left(-\otimes^{L}-\right)$ and $c_{n} \otimes^{L} c_{n^{\prime}} \longrightarrow c_{n+n^{\prime}}\left(-\otimes^{L}-\right)$ on $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ is proven in [HK06, 1.6].

To show that the natural transformations are also defined on DM, fix integers $n, n^{\prime}$, and let $(M, m)$ and ( $M^{\prime}, m^{\prime}$ ) be two objects in DM. Since $\left(M^{\prime}, m^{\prime}\right) \cong\left(M(k)^{\prime}, m^{\prime}-k\right)$, we may assume without loss of generality that $m=m^{\prime}<\min \left(n, n^{\prime}, n+n^{\prime}\right)$. In this case, notice that

$$
\nu^{n}(M, m)=\left(\nu^{n-m} M, m\right) \text { and } \nu^{n^{\prime}}\left(M^{\prime}, m\right)=\left(\nu^{n^{\prime}-m} M^{\prime}, m\right),
$$

and

$$
c_{n}(M, m)=\nu^{n-m}(M)[-n] \text { and } c_{n^{\prime}}(M, m)=\nu^{n^{\prime}-m}(M)\left[-n^{\prime}\right]
$$

Define

$$
\nu^{n}(M, m) \otimes^{L} \nu^{n^{\prime}}\left(M^{\prime}, m\right) \longrightarrow \nu^{n+n^{\prime}}\left((M, m) \otimes^{L}\left(M^{\prime}, m\right)\right)
$$

to be

$$
\left(\nu^{n-m}(M) \otimes^{L} \nu^{n^{\prime}-m}, 2 m\right) \longrightarrow\left(\nu^{n+n^{\prime}-2 m}\left(M \otimes^{L} M^{\prime}\right), 2 m\right)
$$

and

$$
c_{n}(M, m) \otimes^{L} c_{n^{\prime}}\left(M^{\prime}, m\right) \longrightarrow c_{n+n^{\prime}}\left((M, m) \otimes^{L}\left(M^{\prime}, m\right)\right)
$$

to be

$$
c_{n-m} M[-n] \otimes^{L} c_{n^{\prime}-m} M^{\prime}\left[-n^{\prime}\right] \longrightarrow c_{n+n^{\prime}-2 m} M\left[-\left(n+n^{\prime}\right)\right] .
$$

Both maps are independent of the choice of $m$. Naturality in $(M, m)$ and $\left(M^{\prime}, m\right)$ follows from the naturality in $M$ and $M^{\prime}$.

Remark 5.4.6. Notice that the fundamental invariants $c_{k}$ of the slice filtration on $\mathbf{D M}$ always take value in $\mathbf{D M}^{\text {eff,- }}$. More specifically, the fundamental invariants always take value in the full subcategory of birational motives defined in [ KaSu ]. This is established for the fundamental invariants for $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ in [HK06, Section 2], and can be extended directly to DM.

## Chapter 6

## Filtrations on HI

The purpose of this chapter is to construct three filtrations of HI. The main result of this chapter is that there is a sequence of coradicals (see Definition 2.1.3) on the category HI which induces a descending strong filtration and an ascending cofiltration (see Definition 6.2.5 below) of HI by the associated subcategories (see Theorem 6.2.10). The key ingredient in the constructions of the filtrations is the tensor monoidal structure on HI and the partial internal hom. These structures are induced by the tensor and partial internal hom operators on $\mathbf{D} \mathbf{M}^{\text {eff,- }}$ introduced in Section 4.2. All uncredited results in this section are new.

### 6.1 Tensor and partial internal hom structure on HI

To simplify the definition and the proofs in this chapter and the next, we invoke Theorem 4.1.8 and identify the category $\mathbf{D M}{ }^{\text {eff,-- }}$ with the full triangulated subcategory $\mathscr{L}$ of $\mathbb{A}^{1}$-local complexes from Definition 4.1.4. We identify objects $M$ in $\mathbf{D M}{ }^{\text {eff,-- }}$ with bounded above complexes $F^{*}$ of Nisnevich sheaves with transfers such that $H^{n} F^{*}$ is a homotopy invariant presheaf with transfers for every $n$. In particular, regarding a sheaf with transfers as a cochain complex concentrated in degree 0 , we consider HI as an additive subcategory of $\mathbf{D M}^{\text {eff,- }}$.

Recall the following notions from [BBD, 1.3]:
Definition 6.1.1. A $t$-category is a triangulated category $\mathbf{D}$ together with a pair of full subcategories ( $\mathbf{D}^{\geq 0}, \mathbf{D}^{\leq 0}$ ), called the positive objects and negative object of $\mathbf{D}$ respective, which satisfies the following properties:

1. For all $X$ in $\mathbf{D}^{\leq 0}$, and $Y$ in $\mathbf{D}^{\geq 1}, \operatorname{Hom}_{\mathbf{D}}(X, Y)=0$.
2. $\mathbf{D}^{\leq 0} \subset \mathbf{D}^{\leq 1}$ and $\mathbf{D}^{\geq 1} \subset \mathbf{D}^{\geq 0}$
3. For all $X$ in $\mathbf{D}$, there exists a distinguished triangle

$$
A \longrightarrow X \longrightarrow B \longrightarrow A[1]
$$

such that $A$ is in $\mathbf{D}^{\leq 0}$ and $B$ is in $\mathbf{D}^{\geq 1}$.

Here we write $\mathbf{D}^{\geq n}$ and $\mathbf{D}^{\leq n}$ for $\mathbf{D}^{\geq 0}[n]$ and $\mathbf{D}^{\leq 0}[n]$ respectively. We call the pair $\left(\mathbf{D}^{\geq 0}, \mathbf{D}^{\leq 0}\right)$ a $t$-structure on $\mathbf{D}$.

The heart of a $t$-category is the full subcategory $\mathscr{C} \stackrel{\text { def }}{=} \mathbf{D}^{\geq 0} \cap \mathbf{D}^{\leq 0}$.

If $\mathbf{D}$ is a $t$-category, then the inclusion of $\mathbf{D}^{\leq n}$ in $\mathbf{D}$ admits a right adjoint $\tau_{\leq n}$ : $\mathbf{D} \longrightarrow \mathbf{D}^{\leq n}$, and the inclusion of $\mathbf{D}^{\geq n}$ in $\mathbf{D}$ admits left adjoint $\tau_{\geq n}: \mathbf{D} \longrightarrow \mathbf{D}^{\geq n}$. Furthermore, for all $X$ in $\mathbf{D}$, there exists a unique map $d$ in $\operatorname{Hom}_{\mathbf{D}}\left(\tau_{\geq 1} X, \tau_{\leq 0} X[1]\right)$ such that

$$
\tau_{\leq 0} X \longrightarrow X \longrightarrow \tau_{\geq 1} X \xrightarrow{d} \tau_{\leq 0} X[1]
$$

is distinguished (see [BBD, 1.3.3]). For integers $m$ and $n$ such that $m<n, \tau_{\leq m} \tau_{\leq n}=$ $\tau_{\leq n} \tau_{\leq m}=\tau_{\leq m}$, and $\tau_{\geq m} \tau_{\geq n}=\tau_{\geq n} \tau_{\geq m}=\tau_{\geq n}$. Furthermore, $\tau_{\leq m} \tau_{\geq n}=\tau_{\geq n} \tau_{\leq m}=0$, and $\tau_{\leq n} \tau_{\geq m}=\tau_{\geq m} \tau_{\leq n}$ (see [BBD, 1.3.5]). When $n=m=0$, the composition $\tau_{\leq 0} \tau_{\geq 0}$ defines an additive functor $\mathbf{H}^{0}: \mathbf{D} \longrightarrow \mathscr{C}$.

Recall from [BBD, 1.2.5] that an abelian subcategory $\mathscr{C}$ of $\mathbf{D}$ is admissible if for all $C$ and $D$ in $\mathscr{C}$ and $i<0, \operatorname{Hom}_{\mathbf{D}}(C, D[i])=0$, and all exact sequences in $\mathscr{C}$ come from distinguished triangles in $\mathbf{D}$.

Theorem 6.1.2 ([BBD] 1.3.6). Let $\mathbf{D}$ be a $t$-category, and let $\left(\mathbf{D}^{\geq 0}, \mathbf{D}^{\leq 0}\right)$ be its associated $t$ structure. Then the heart $\mathscr{C}$ is an admissible abelian category, stable under taking extensions.

Example 6.1.3 ([BBD] 1.3.2). Let $\mathscr{A}$ be an abelian category, and $\mathbf{D} \mathscr{A}$ be its derived category. There is a natural $t$-structure on $\mathbf{D} \mathscr{A}$. The pair $\left(\mathbf{D} \mathscr{A}^{\geq 0}, \mathbf{D} \mathscr{A} \leq 0\right)$ is a pair of full subcategories whose objects are those with trivial cohomology in the negative and positive degrees respectively. In this case, the functors $\tau_{\geq n}$ and $\tau_{\leq n}$ are given by good truncations.

The heart of this $t$-structure is precisely $\mathscr{A}$, where an object of $\mathscr{A}$ is regarded as a complex concentrated in degree 0 . (See the example following the statement of 1.3.6 in [BBD].)

Example 6.1.4 ([BBD] 1.3.16). If $\mathbf{D}^{\prime}$ is a full triangulated subcategory of a $t$-category $\mathbf{D}$, then $\mathbf{D}^{\prime}$ is also a $t$-category with the $t$-structure given by $\left(\mathbf{D}^{\prime \geq 0}, \mathbf{D}^{\prime \leq 0}\right)$, where $\mathbf{D}^{\geq 0} \stackrel{\text { def }}{=} \mathbf{D}^{\geq 0} \cap \mathbf{D}$ and $\mathbf{D}^{\prime \leq 0} \stackrel{\text { def }}{=} \mathbf{D}^{\leq 0} \cap \mathbf{D}^{\prime}$.

Definition 6.1.5. Let $\varphi: \mathbf{D} \longrightarrow \mathbf{D}^{\prime}$ be a triangulated functor between $t$-categories. We say that $\varphi$ is right $t$-exact if $\varphi\left(\mathbf{D}^{\leq 0}\right) \subseteq \mathbf{D}^{\prime \leq 0}$, and left $t$-exact if $\varphi\left(\mathbf{D}^{\geq 0}\right) \subseteq \mathbf{D}^{\prime \geq 0}$. We say that $\varphi$ is $t$-exact if it is both right and left $t$-exact.

The concept of (left or right) $t$-exactness is a generalization of exactness in abelian category. We have the following result regarding $t$-exact functors and the induced functor on the hearts.

Proposition 6.1.6 ([BBD] 1.3.17). Let $\mathbf{D}$ and $\mathbf{D}^{\prime}$ be t-categories with hearts $\mathscr{A}$ and $\mathscr{A}^{\prime}$ respectively. Furthermore, let $F: \mathbf{D} \longrightarrow \mathbf{D}^{\prime}$ be a left (resp., right) t-exact triangulated functor. Then $\mathbf{H}^{0} F$ is a left (resp., right) exact functor from $\mathscr{A}$ to $\mathscr{A}^{\prime}$.

If a $t$-category $\mathbf{D}$ is equipped with an additive symmetric monoidal structure that is right $t$-exact in both factors, then so is its heart $\mathscr{C}$. The symmetric monoidal structure on the heart is defined as follows. Suppose $-\otimes-$ is the tensor operator on D. For $C, C^{\prime}$ in $\mathscr{C}$, we define $C \otimes^{\mathscr{C}} C^{\prime}$ by $\mathbf{H}^{0}\left(C \otimes C^{\prime}\right)$. Since $\otimes$ is right $t$-exact in both factors, for all $M$ and $N$ in $\mathbf{D}^{\leq 0}$,

$$
\mathbf{H}^{0}(M \otimes N)=\mathbf{H}^{0}\left(\mathbf{H}^{0}(M) \otimes \mathbf{H}^{0}(N)\right)
$$

([Dég10, 5.10]) and $\otimes^{\mathscr{C}}$ is well-defined. It is now straightforward to verify that $\left(\mathscr{C}, \otimes^{\mathscr{C}}\right.$ ) satisfies all the axioms of a symmetric monoidal category.

In addition, if $\mathbf{D}$ has a partial internal hom structure ( $\mathrm{Hom}, \mathbf{D}^{\text {rep }}$ ) as defined in Definition 4.2.2, then $\mathscr{C}$ is also equipped with a partial internal hom. For $C, C^{\prime}$ in $\mathscr{C}$, let us set

$$
\underline{\operatorname{Hom}}_{\mathscr{C}}\left(C, C^{\prime}\right) \stackrel{\text { def }}{=} \mathbf{H}^{0}\left(\underline{\operatorname{Hom}}\left(C, C^{\prime}\right)\right)
$$

Proposition 6.1.7. Let $C$ be an object in $\mathbf{D}^{\text {rep }} \cap \mathscr{C}$ such that $\underline{H o m}(C,-)$ is right $t$-exact. Then $\underline{\operatorname{Hom}}_{\mathscr{C}}(C,-)$ is right adjoint to $C \otimes^{\mathscr{C}}$ - as endofunctors on $\mathscr{C}$.

Proof. Notice that for $M$ in $\mathbf{D}^{\leq 0}$ and $M^{\prime}$ in $\mathbf{D}^{\geq 0}$,

$$
\begin{equation*}
\operatorname{Hom}_{\mathbf{D}}\left(\mathbf{H}^{0}(M), M^{\prime}\right) \cong \operatorname{Hom}_{\mathbf{D}}\left(M, M^{\prime}\right) \tag{6.1.8}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{Hom}_{\mathbf{D}}\left(M, \mathbf{H}^{0}\left(M^{\prime}\right)\right) \cong \operatorname{Hom}_{\mathbf{D}}\left(M, M^{\prime}\right) \tag{6.1.9}
\end{equation*}
$$

Fix any $C_{1}, C_{2}$ in $\mathscr{C}$. Since $\otimes$ is right $t$-exact in both factors, $C_{1} \otimes C$ is in $\mathbf{D}^{\leq 0}$, and using the isomorphism in (6.1.8), we obtain the following isomorphism:

$$
\operatorname{Hom}_{\mathscr{G}}\left(C_{1} \otimes^{\mathscr{C}} C, C_{2}\right)=\operatorname{Hom}_{\mathscr{C}}\left(\mathbf{H}^{0}\left(C_{1} \otimes C\right), C_{2}\right) \cong \operatorname{Hom}_{\mathbf{D}}\left(C_{1} \otimes C, C_{3}\right)
$$

Since $C$ is in $\mathbf{D}^{\text {rep }}$, the functor $-\otimes C$ is left adjoint to $\operatorname{Hom}(C,-)$. By assumption, $\underline{\operatorname{Hom}}(C,-)$ is right $t$-exact, and since $C_{2}$ is in the heart, $\underline{\operatorname{Hom}\left(C, C_{2}\right) \text { is an object in }}$ $\mathbf{D}^{\geq 0}$. Therefore, using the isomorphism in (6.1.9), we obtain the following chain of isomorphisms:

$$
\begin{aligned}
\operatorname{Hom}_{\mathscr{C}}\left(C_{1} \otimes^{\mathscr{C}} C, C_{2}\right) & \cong \operatorname{Hom}_{\mathbf{D}}\left(C_{1} \otimes C, C_{2}\right) \\
& \cong \operatorname{Hom}_{\mathbf{D}}\left(C_{1}, \underline{\operatorname{Hom}}\left(C, C_{2}\right)\right) \\
& \cong \operatorname{Hom}_{\mathbf{D}}\left(C_{1}, \mathbf{H}^{0}\left(\underline{\operatorname{Hom}}\left(C, C_{2}\right)\right)\right) \\
& =\operatorname{Hom}_{\mathscr{C}}\left(C_{1}, \underline{\operatorname{Hom}}_{\mathscr{C}}\left(C, C_{2}\right)\right)
\end{aligned}
$$

Since each of the above isomorphism is natural in $C_{1}$ and $C_{2}$, the proposition now follows.

Proposition 6.1.7 shows that the functor $\underline{\operatorname{Hom}}_{\mathscr{C}}$ defines a partial internal hom on the category $\mathscr{C}$ where the collection of semi-representable objects of $\underline{H o m}_{\mathscr{C}}$ contains at

The above discussion applies to the category $\mathbf{D M}{ }^{\text {eff,- }}$ since there exists a $t$-structure on $\mathbf{D} \mathbf{M}^{\mathrm{eff},-}$, with the abelian category $\mathbf{H I}$ as its heart (see Theorem 4.1.8).

Definition 6.1.10. We write $\tau_{\leq 0} \mathbf{D} \mathbf{M}^{\text {eff,- }}$ for the negative objects of $\mathbf{D} \mathbf{M}^{\text {eff,- }}$, and $\tau_{\geq 0} \mathbf{D M}{ }^{\text {eff,- }}$ for the positive objects of $\mathbf{D M}^{\text {eff,- }}$. We will also let $\tau_{\leq 0}, \tau_{\geq 0}$ and $\mathbf{H}^{0}$ denote the functors from $\mathbf{D} M^{\text {eff,- }}$ to $\tau_{\leq 0} \mathbf{D M}^{\text {eff,- }}, \tau_{\geq 0} \mathbf{D M}^{\text {eff,- }}$ and $\mathbf{H I}$, respectively.

The triangulated monoidal structure on $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$ induces a symmetric monoidal bifunctor on $\mathbf{H I}$, which we write as $\otimes^{H}$. This bifunctor is uniquely characterized by

$$
h_{X} \otimes^{H} h_{Y}=h_{X \times Y},
$$

where $h_{X}=\mathbf{H}^{0}(M(X))$ for $X$ in $\operatorname{Sm}_{k}($ see [Dég10, 1.8]).
Moreover, there is a partial internal hom, defined by

$$
\underline{\operatorname{Hom}}_{\mathbf{H I}}(F, G)=\mathbf{H}^{0}\left(\underline{\mathrm{RHom}}_{\mathbf{D M}}{ }^{\text {eff },-}(F, G)\right)
$$

for all $G$ in $\mathbf{H I}$, and $F$ in $\mathbf{H I} \cap \mathbf{D M}_{g m}^{\text {eff,- }}$ for which $\underline{\mathrm{RHom}}_{\mathbf{D M}^{\text {eff, }}}(F,-)$ is left $t$-exact. Our first goal is to show that $\mathcal{O}^{*}$ is semi-representable with respect to $\underline{H o m}_{\mathbf{H I}}$ by showing that $\underline{\text { RHom }}_{\mathbf{D M}^{\text {eff,- }}}\left(\mathcal{O}^{*},-\right)$ is right $t$-exact. This is established by the following lemma. Recall from Definition 3.2.7 that for $F$ in $\mathbf{H I}, F_{-1}$ is the contraction of $F$, which is the homotopy invariant sheaf with transfers defined by

$$
X \mapsto \operatorname{cok}\left(F\left(X \times \mathbb{A}^{1}\right) \longrightarrow F\left(X \times\left(\mathbb{A}^{1}-0\right)\right)\right) .
$$

Moreover, $F \mapsto F_{-1}$ defines an endofunctor on HI.
Lemma 6.1.11. There exists a natural isomorphism of homotopy invariant sheaves with transfers

$$
\mathbf{H}^{i} \underline{\mathrm{RHom}}_{\mathbf{D M}^{\mathrm{eff}},-}(\mathbb{Z}(n)[n], M) \cong\left(\mathbf{H}^{i} M\right)_{-n} .
$$

In particular, $\underline{\mathrm{RHom}}_{\mathbf{D M}^{\mathrm{eff}},-\left(\mathcal{O}^{*},-\right) \text { is left } t \text {-exact. }}$
Proof. Fix an object $M$ in $\mathbf{D} \mathbf{M}^{\text {eff,- }}$, regarded as a cochain complex of sheaves with transfers with homotopy invariant cohomology presheaves. By [Dég08, 3.4.4], there exists a natural morphism between homotopy invariant presheaves with transfers:

$$
i:\left(H^{i} M\right)_{-n} \longrightarrow H^{i} \underline{\mathrm{RHom}}_{\mathbf{D M}^{\mathrm{eff}},-}(\mathbb{Z}(n)[n], M)
$$

such that for all fields $E$ over $k$, the following is an isomorphism:

$$
\left(H^{i} M\right)_{-n}(\operatorname{Spec} E) \cong H^{i} \underline{\mathrm{RHom}}_{\mathbf{D M}^{\mathrm{eff}},--}(\mathbb{Z}(n)[n], M)(\operatorname{Spec} E) .
$$

By [MVW, 11.2], $i$ induces a natural isomorphism of the associated homotopy invariant Nisnevich sheaves with transfers:

$$
\left(\mathbf{H}^{i} M\right)_{-n} \xrightarrow{\cong} \mathbf{H}^{i} \underline{R H o m}_{\mathbf{D M}^{\mathrm{eff},-}}(\mathbb{Z}(n)[n], M) .
$$

This proves the first claim in the Lemma.
To see that $\underline{\text { RHom }}_{\mathbf{D M}^{\text {eff, }}}\left(\mathcal{O}^{*},-\right)$ is left $t$-exact, suppose $M$ is a positive object, i.e., $\mathbf{H}^{i} M=0$ for all $i<0$. Since $\mathcal{O}^{*} \cong \mathbb{Z}(1)[1]$, applying the above for $n=1$, we see that for all $i<0$,

$$
\mathbf{H}^{i} \underline{\mathrm{RHom}}_{\mathbf{D}}{ }^{\text {eff },-}\left(\mathcal{O}^{*}, M\right) \cong \mathbf{H}^{i} \underline{\mathrm{RHom}}_{\mathbf{D M}}{ }^{\text {eff },-}(\mathbb{Z}(1)[1], M) \cong\left(\mathbf{H}^{i} M\right)_{-1}=0 .
$$

Thus, $\underline{R H o m}_{\mathbf{D M}}{ }^{\text {eff,- }}\left(\mathcal{O}^{*}, M\right)$ is also a positive object in $\mathbf{D M}^{\text {eff,-- }}$, and the lemma is now established.

Definition 6.1.12. To emphasize the relationship with corresponding operations in $\mathbf{D M}^{\text {eff,-, }}$, let us set

$$
F(1)^{\mathrm{HI}} \stackrel{\text { def }}{=} F \otimes^{H} \mathcal{O}^{*} \quad \text { and } \quad F_{-1}^{\mathrm{HI}} \stackrel{\text { def }}{=} \underline{\operatorname{Hom}}_{\mathbf{H I}}\left(\mathcal{O}^{*}, F\right) .
$$

We write $F(n)^{\mathrm{HI}}$ for $\left(F(n-1)^{\mathrm{HI}}\right)(1)^{\mathrm{HI}}$ and $F_{-n}^{\mathrm{HI}}$ for $\left(F_{-n+1}^{\mathrm{HI}}\right)_{-1}^{\mathrm{HI}}$.
By Lemma 6.1.11 and preceding comments, $F \mapsto F(1)^{\mathrm{HI}}$ is left adjoint to $F \mapsto F_{-1}^{\mathrm{HI}}$, and therefore $F \mapsto F(n)^{\mathrm{HI}}$ is left adjoint to $F \mapsto F_{-n}^{\mathrm{HI}}$ for all $n>0$.

Remark 6.1.13. To simplify notation, we will drop the "HI", and simply write $F(n)$ and $F_{-n}$ for $F(n)^{\mathrm{HI}}$ and $F_{-n}^{\mathrm{HI}}$. Doing so introduces a number of potential sources of ambiguity. The first is that $F(n)$ is already used to represent $F \otimes^{L} \mathbb{Z}(n)$, where $\mathbb{Z}(n)$ is the motivic complex in $\mathbf{D M}{ }^{\text {eff,-- }}$ introduced in Section 4.3. In particular, $\mathbb{Z}(n)$ may refer to the motivic complexes as well as the objects $\mathbb{Z} \otimes^{H}\left(\mathcal{O}^{*}\right)^{\otimes n}$. To resolve this ambiguity, we adopt the following convention: For the remainder of the thesis, unless otherwise specified, for an object $F$ in $\mathbf{H I}, F(n)$ will denote $F(n)^{\mathrm{HI}} \stackrel{\text { def }}{=} F \otimes^{H}\left(\mathcal{O}^{*}\right)^{\otimes n}$. All mentions of $\mathbb{Z}(n)$ will refer to the motivic complex in $\mathbf{D M}{ }^{\text {eff,- }}$.

The second source of potential ambiguity comes from the fact that $F_{-1}$ is already used to represent the contraction of the sheaf $F$ in HI. Recall from Definition 3.2.7 that $F_{-1}$ is the sheaf that sends $X$ in $\mathrm{Sm}_{k}$ to cok $p^{*}$, where

$$
p^{*}: F(X) \longrightarrow F\left(X \times\left(\mathbb{A}^{1}-0\right)\right)
$$

is the map induced by the projection $X \times\left(\mathbb{A}^{1}-0\right) \longrightarrow X$. In fact, there is no ambiguity here, since the contraction of $F$ is isomorphic to the sheaf $\underline{\operatorname{Hom}}_{\mathbf{H I}}\left(\mathcal{O}^{*}, F\right)$. Indeed, by
[Dég08, 3.4.5], the contraction of $F$ is isomorphic to $\underline{R H o m}_{\mathbf{D M}^{\text {eff,-- }}}(\mathbb{Z}(1)[1], F)$. Recall from $[\mathrm{MVW}, 4.1]$ that $\mathbb{Z}(1)[1] \cong \mathcal{O}^{*}$ in $\mathbf{D M}^{\text {eff,-- }}$. Hence, we have that

$$
\underline{\operatorname{Hom}}_{\mathbf{H I}}\left(\mathcal{O}^{*}, F\right) \cong \mathbf{H}^{0} \underline{\mathrm{RHom}}_{\mathbf{D M}^{\mathrm{eff},--}}(\mathbb{Z}(1)[1], F) \cong \mathbf{H}^{0} F_{-1}=F_{-1} .
$$

Finally, we make some observations that will be useful in subsequent sections.

Proposition 6.1.14. For all negative objects $M$,

$$
\mathbf{H}^{0}\left(M \otimes^{L} \mathbb{Z}(n)[n]\right)=\mathbf{H}^{0}(M)(n) .
$$

Proof. By construction, the tensor operation $\otimes^{L}$ is right $t$-exact in both factors. Therefore, for negative objects $M$ and $N$ of $\mathbf{D M}^{\text {eff,-- }}$, we have that

$$
\mathbf{H}^{0} M \otimes^{H} \mathbf{H}^{0} N=\mathbf{H}^{0}\left(\mathbf{H}^{0}(M) \otimes^{L} \mathbf{H}^{0}(N)\right)=\mathbf{H}^{0}\left(M \otimes^{L} N\right) .
$$

Since $\mathbb{Z}(n)[n]=\mathbb{Z}(n-1)[n-1] \otimes^{L} \mathbb{Z}(1)[1]$, and $\mathbb{Z}(1)[1] \cong \mathcal{O}^{*}$, by induction on $n, \mathbb{Z}(n)[n]$ is also a negative object and $\mathbf{H}^{0}(\mathbb{Z}(n)[n]) \cong\left(\mathcal{O}^{*}\right)^{\otimes n}$. Moreover, for a negative object $M$ in $\mathbf{D M}{ }^{\text {efff,- }}$, we obtain the following:

$$
\mathbf{H}^{0}\left(M \otimes^{L} \mathbb{Z}(n)[n]\right) \cong \mathbf{H}^{0}(M) \otimes^{H}\left(\mathcal{O}^{*}\right)^{\otimes n}=\mathbf{H}^{0}(M)(n) .
$$

Proposition 6.1.15. Let $F$ be a homotopy invariant sheaf with transfers. The unit map $F \longrightarrow F(n)_{-n}$ is an isomorphism.

Proof. For $F$ in HI, by the Cancellation Theorem 4.4.1, we have that

$$
\underline{\operatorname{RHom}}_{\mathbf{D M}^{\mathrm{eff},-}}(\mathbb{Z}(n)[n], F(n)[n]) \cong \underline{\operatorname{RHom}}_{\mathbf{D M}^{\mathrm{eff}},-}(\mathbb{Z}, F) \cong F \text {. }
$$

Now apply $\mathbf{H}^{0}$ to this chain of isomorphisms. Using Lemma 6.1.11 and the fact that $\mathbf{H}^{0}(F)=F$, we obtain the desired isomorphism.

Proposition 6.1.16. If $F=G(n)$ for some $G$ in $\mathbf{H I}$, then $\epsilon_{F}^{n}: F_{-n}(n) \longrightarrow F$ is an isomorphism.

Proof. Suppose $F=G(n)$ for some $G$ in HI. Writing $L$ for the functor $F \mapsto F(n)$, by counit-unit adjunction, the composition

$$
G(n) \xrightarrow{L \eta_{G}}\left(G(n)_{-n}\right)(n) \xrightarrow{\epsilon_{G} L} G(n)
$$

is the identity, where $\eta_{G}$ and $\epsilon_{G}$ are the unit and the counit maps respectively. By Proposition 6.1.15, $\eta_{G}$ is an isomorphism, and so is $L \eta_{G}$. It follows that $\epsilon_{G} L$ is an isomorphism as well. Since $\epsilon_{G} L$ is the counit map for $L G=G(n)=F$, the proposition follows.

### 6.2 Torsion filtration on HI

We now define the first filtration on $\mathbf{H I}$. Let $\mathbf{H I}(0)=\mathbf{H I}$ and let $\mathbf{H I}(n)$ denote the full subcategory of objects $F$ where $F \cong F^{\prime}(n)$ for some $F^{\prime}$ in HI. It is clear that if $m \geq n$, then $\mathbf{H I}(m) \subseteq \mathbf{H I}(n)$. In particular, we have a tower of subcategories

$$
\mathbf{H I}=\mathbf{H I}(0) \supset \mathbf{H I}(1) \supset \mathbf{H I}(2) \subset \cdots .
$$

To see that this filtration is not trivial (i.e., $\mathbf{H I}(n) \neq \mathbf{H I}(m)$ for all natural numbers $n \neq m$ ), notice that for the constant sheaf $\mathbb{Z}$, it is clear that $\mathbb{Z}_{-1}=0$. Then $\mathbb{Z}$ is an object in $\mathbf{H I}$ but not in $\mathbf{H I}(1)$. Indeed, if $\mathbb{Z} \in \mathbf{H I}(1)$ then $\mathbb{Z} \cong F^{\prime}(1)$, but then $\mathbb{Z}_{-1}=F^{\prime}$ by Proposition 6.1.15, forcing $\mathbb{Z}=0$. Similarly, since $\mathcal{O}_{-1}^{*}=\mathbb{Z}, \mathcal{O}^{*} \in \mathbf{H I}(1)$ but $\mathcal{O}^{*} \notin \mathbf{H I}(2)$. In general, $\mathcal{O}^{*}(n-1)$ is an object of $\mathbf{H I}(n)$ but not $\mathbf{H I}(n+1)$.

Remark 6.2.1. The subcategories $\mathbf{H I}(n)$ are additive, but not abelian, except for the case $n=0$. To see this, consider the map

$$
n: \mathcal{O}^{*} \longrightarrow \mathcal{O}^{*}
$$

given by sending $u \in \mathcal{O}^{*}(X)$ to $u^{n}$ for each $X$ in $\operatorname{Sm}_{k}$. The kernel of this map is the sheaf of $n$-th roots of unity $\mu_{n}$. But $\left(\mu_{n}\right)_{-1}=0$. If $\mu_{n}$ were in $\mathbf{H I}(n)$, then by Proposition 6.1.16, we would have $\mu_{n} \cong\left(\mu_{n}\right)_{-1}(1)=0$, which is a contradiction. It follows that $\mathbf{H I}(1)$ is not closed under kernels. Similar arguments show that $\mathbf{H I}(n)$ is not closed under kernel for any positive integer $n$.

Recall from Definition 5.0.1 that a descending weak filtration $\left(\mathscr{A}_{*}, \varphi_{*}\right)$ is a tower of subcategories $\mathscr{A}_{i}$ together with coreflection functors $\varphi_{i}: \mathscr{A} \longrightarrow \mathscr{A}_{i}$ such that $\varphi_{i}$ restricted to $\mathscr{A}_{i}$ is naturally isomorphic to the identity. To show that the full subcategories $\mathbf{H I}(n)$ define a descending weak filtration, we need to show that there exist coreflection functors $\sigma^{n}: \mathbf{H I} \longrightarrow \mathbf{H I}(n)$.

Definition 6.2.2. Let $\sigma^{n}$ denote the functor $F \mapsto\left(F_{-n}\right)(n)$. Since $F \mapsto F(n)$ is right exact, and $F_{-n}$ is exact (Proposition 3.2.8), $\sigma^{n}$ is right exact. However, $\sigma^{n}$ is not always left exact (see Example 6.2.4 below).

Proposition 6.2.3. The functor $\sigma^{n}$ is right adjoint to the inclusion of $\mathbf{H I}(n)$. In particular, $\left(\mathbf{H I}(*), \sigma^{*}\right)$ defines a (nontrivial) descending weak filtration of $\mathbf{H I}$.

Proof. Let $f: F \longrightarrow G$ be a map in $\mathbf{H I}$, with $F$ in $\mathbf{H I}(n)$, and let $\epsilon^{n}$ denote the counit $\sigma^{n} \longrightarrow \mathrm{id}$. By naturality of $\epsilon^{n}$, we have the following commutative diagram:

Since $F \in \mathbf{H I}(n)$, by Proposition 6.1.16 the counit map $\epsilon_{F}^{n}$ is an isomorphism.
Define the map $\chi: \operatorname{Hom}_{\mathbf{H I}}(F, G) \longrightarrow \operatorname{Hom}_{\mathbf{H I}(n)}\left(F, G_{-n}(n)\right)$ by $f \mapsto \epsilon^{n} f \circ\left(\epsilon_{F}^{n}\right)^{-1}$. Since $\epsilon_{G}^{n} \circ \chi(f)=f, \chi$ is injective. Moreover, given a map $g: F \longrightarrow G_{-n}(n)$, set $f^{\prime}=\epsilon_{G}^{n} \circ g$. Then $\chi\left(f^{\prime}\right)=g$. Hence $\chi$ is an isomorphism as desired. From the way $\chi$ is defined, it is clear that $\chi$ is functorial in both $F$ and $G$, and therefore $\sigma^{n}$ is right adjoint to the inclusion of $\mathbf{H I}(n)$ into $\mathbf{H I}$.

To show that $\left(\mathbf{H I}(*), \sigma^{*}\right)$ define a weak descending filtration, the only criterion left to check is that $\sigma^{n}$ restricted to $\mathbf{H I}(n)$ is naturally isomorphic to the identity. By Proposition 6.1.16, the counit map $\epsilon^{n}: \sigma^{n} F \longrightarrow F$ is an isomorphism for all $F$ in $\mathbf{H I}(n)$, and the proposition follows.

Example 6.2.4. While $\left(\mathbf{H I}(*), \sigma^{*}\right)$ forms a weak filtration of $\mathbf{H I}$, for a given sheaf $F$ in HI, the objects $\sigma^{n} F$ are not in general subobjects of $F$, because the counit map $\sigma^{n} F \longrightarrow F$ is not always injective. Here is an example.

Let $\mathcal{O}^{* n}$ be the sheaf of $n$-th power of global units associated to the presheaf where sections of a smooth finite type $k$-scheme $X$ is the abelian subgroup of $\mathcal{O}^{*}$ given by

$$
\mathcal{O}^{* n}(X)=\left\{x: x=y^{n} \text { for some } y \text { in } \mathcal{O}^{*}(X)\right\}
$$

It is clear that $\mathcal{O}^{* n} \in \mathbf{H I}$. Furthermore, there exists the following exact sequence

$$
0 \longrightarrow \mu_{n} \longrightarrow \mathcal{O}^{*} \longrightarrow \mathcal{O}^{* n} \longrightarrow 0
$$

where $\mu_{n}$ is the constant sheaf of $n$-th roots of unity. In particular, $\left(\mu_{n}\right)_{-1}=0$. By Proposition 3.2.8, the functor $F \mapsto F_{-1}$ is exact. Therefore, the map $\mathcal{O}_{-1}^{*} \longrightarrow\left(\mathcal{O}^{* n}\right)_{-1}$ is an isomorphism, and

$$
\left(\mathcal{O}^{* n}\right)_{-1}(1) \cong \mathcal{O}_{-1}^{*}(1)=\mathcal{O}^{*}
$$

and the counit $\left(\mathcal{O}^{* n}\right)_{-1}(1) \longrightarrow \mathcal{O}^{* n}$ is given precisely by $x \mapsto x^{n}$, which has a nontrivial kernel.

We can understand the problem in another way, which is that the categories $\mathbf{H I}(*)$ are too small and do not include all the kernels of counits $\left(F_{-n}\right)(n) \longrightarrow F$. This can be fixed by enlarging the filtration at each level, and to do so, we turn to torsion theory.

Motivated by Example 6.2.4, we introduce the following more stringent criteria on weak filtrations.

Definition 6.2.5. Let $\mathscr{A}$ be an abelian category. We say that a $\mathbb{Z}$-indexed descending weak filtration $\left(\mathscr{A}_{*}, \varphi_{*}\right)$ is a strong filtration if for each $A$ in $\mathscr{A}$ and $n$ in $\mathbb{Z}, \varphi_{n} A \longrightarrow A$ is a monomorphism of $A$. An ascending weak filtration $\left(\mathscr{A}_{*}, \varphi_{*}\right)$ is a strong cofiltration if $A \longrightarrow \varphi_{n} A$ is a quotient of $A$ for each $n$ and each $A$ in $\mathscr{A}$.

Similarly, we can define ascending strong filtration and descending strong cofiltration on $\mathscr{A}$.

Example 6.2.6. Here is an example of a strong ascending filtration and a strong descending filtration on the category $\mathbf{Q C}$ of quasi-coherent sheaves on $\mathbb{P}^{n}$. Let $i_{k}$ denote the closed immersion of $\mathbb{P}^{k}$ into $\mathbb{P}^{n}$ as a subscheme identified by the vanishing of the last $n-k$ homogeneous coordinates, and let $j_{k}$ denote the open immersion of $U_{k} \stackrel{\text { def }}{=} \mathbb{P}^{n}-\mathbb{P}^{k}$ into $\mathbb{P}^{n}$.

Let $\mathbf{Q C}{ }^{k}$ be the full subcategory of quasi-coherent sheaves on $\mathbb{P}^{n}$ supported in $U_{k}$ and let $\mathbf{Q C}_{k}$ denote the full subcategory of sheaves on $\mathbb{P}^{n}$ supported in $\mathbb{P}^{k}$. Since

$$
U_{0} \supseteq U_{1} \supseteq U_{2} \supseteq \cdots \supseteq U_{n}
$$

and

$$
\mathbb{P}^{0} \subseteq \mathbb{P}^{1} \subseteq \mathbb{P}^{2} \subseteq \cdots \subseteq \mathbb{P}^{n}
$$

we have the following towers of subcategories:

$$
\mathbf{Q C}^{0} \supseteq \mathbf{Q C}^{1} \supseteq \mathbf{Q C}^{2} \supseteq \cdots \supseteq \mathbf{Q C}^{n}
$$

and

$$
\mathbf{Q C}_{0} \subseteq \mathbf{Q C}_{1} \subseteq \mathbf{Q C}_{2} \subseteq \cdots \subseteq \mathbf{Q C}_{n}
$$

We will show that the towers of subcategories define a strong filtration and strong cofiltration on QC. For each positive integer $k$ less than $n$ and each $F$ in QC, we have the following exact sequence of quasi-coherent sheaves on $\mathbb{P}^{n}$ :

$$
\begin{equation*}
0 \longrightarrow\left(j_{k}\right)_{!}\left(\left.F\right|_{U}\right) \longrightarrow F \longrightarrow\left(i_{k}\right)_{*}\left(\left.F\right|_{Z}\right) \longrightarrow 0 \tag{6.2.7}
\end{equation*}
$$

where $\left(j_{k}\right)!\left(\left.F\right|_{U}\right)$ is the sheaf associated with the presheaf given by

$$
V \mapsto \begin{cases}F(V) & \text { if } V \subseteq U_{k} \\ 0 & \text { otherwise }\end{cases}
$$

In this case $\left(j_{k}\right)!(F)$ is in $\mathbf{Q C}^{k}$ and $\left(i_{k}\right)_{*}(F)$ is in $\mathbf{Q C}_{k}$ (see [Hart77, Ex. 1.19]). In fact, $F \mapsto\left(j_{k}\right)_{!}\left(\left.F\right|_{U_{k}}\right)$ and $F \mapsto\left(i_{k}\right)_{*}\left(\left.F\right|_{\mathbb{P}^{k}}\right)$ define functors from $\mathbf{Q C}$ to $\mathbf{Q C}{ }^{k}$ and $\mathbf{Q C}_{k}$ respectively. In this case $\left(j_{k}\right)$ ! is right adjoint to inclusion, and $\left(i_{k}\right)_{*}$ is left adjoint to inclusion.

In general, let $Z_{1} \subseteq Z_{2} \subseteq \cdots Z_{n}$ be a sequence of subschemes of some scheme $X$, and let $U_{k}=X-Z_{k}$. Let $\mathbf{Q C}(X)$ be the abelian category of quasi-coherent sheaves on $X$. Then there exists a strong descending filtration

$$
\begin{equation*}
\mathbf{Q C}^{0}(X) \supseteq \mathbf{Q C}^{1}(X) \supseteq \mathbf{Q C}^{2}(X) \supseteq \cdots \supseteq \mathbf{Q C}^{n}(X) \tag{6.2.8}
\end{equation*}
$$

where $\mathbf{Q C}^{k}(X)$ is the full subcategory of quasi-coherent sheaves supported on $U_{k}$, and a strong ascending cofiltration on $\mathbf{Q C}(X)$

$$
\begin{equation*}
\mathbf{Q C}_{0}(X) \subseteq \mathbf{Q C}_{1}(X) \subseteq \mathbf{Q C}_{2}(X) \subseteq \cdots \subseteq \mathbf{Q C}_{n}(X) \tag{6.2.9}
\end{equation*}
$$

where $\mathbf{Q C}_{k}(X)$ is the full subcategory of quasi-coherent sheaves on $X$ supported on $Z_{k}$. As above, the coreflection functors $\varphi^{k}$ from $\mathbf{Q C}$ to $\mathbf{Q} \mathbf{C}^{k}$ are given by $F \mapsto\left(j_{k}\right)!\left(F \mid U_{k}\right)$ where $j_{k}$ is the open immersion $j_{k}: U_{k} \longrightarrow X$; the reflection functors $\varphi_{k}$ from $\mathbf{Q C}$
to $\mathbf{Q C}_{k}$ are given by $F \mapsto\left(i_{k}\right)_{*}\left(\left.F\right|_{Z_{k}}\right)$, where $i_{k}: Z_{k} \longrightarrow X$ is the evident closed immersion. Since, for each $k$, we have an exact sequence of quasi-coherent sheaves as in (6.2.7), $\varphi^{k}(F)$ is a subobject of $F$ and $\varphi_{k}(F)$ is a quotient of $F$ for each $F$ in $\mathbf{Q C}(X)$. The claim that (6.2.8) defines a strong filtration and (6.2.9) defines a strong cofiltration now follows.

We will now state the main theorem. Recall from Theorem 2.2.9 that if $\varphi$ is a coradical, the associated torsion theory is a pair of full subcategories ( $\mathscr{T}, \mathscr{F}$ ) where the torsion subcategory $\mathscr{T}$ consists of the objects $T$ such that $\varphi(T)=0$, and the torsionfree subcategory $\mathscr{F}$ consists of the objects $F$ such that the map $F \longrightarrow \varphi(F)$ is an isomorphism.

Theorem 6.2.10. There exists a sequence of coradicals $\varphi^{<n}, n=0,1,2 \cdots$ on HI such that the associated torsionfree subcategories $\mathbf{H I}{ }^{\geq *}$ form a descending strong filtration of HI and the associated torsion subcategories $\mathbf{H I}{ }^{<*}$ form a strong cofiltration.

Theorem 6.2.10 will be verified by Propositions 6.2 .17 and 6.2 .22 below. We first define the strong cofiltration, and show that the reflection functors are coradicals.

Definition 6.2.11. If $n$ is a natural number, let $\mathbf{H I}^{<n}$ be the full subcategory of objects $F$ in HI such that $F_{-n}=0$. By Proposition 3.2.8, $F \mapsto F_{-n}$ is exact. Therefore, $\mathbf{H I}{ }^{<n}$ is an abelian subcategory closed under extensions.

By convention, define $F_{-0}$ to be $F$. Since $F_{-n-1}=\left(F_{-n}\right)_{-1}$, we obtain the following ascending tower of subcategories

$$
0=\mathbf{H I}^{<0} \subset \mathbf{H I}^{<1} \subset \mathbf{H I}^{<2} \subset \cdots \subset \mathbf{H I}
$$

Since $\mathcal{O}_{-1}^{*}=\mathbb{Z}$ and $\mathbb{Z}_{-1}=0, \mathcal{O}^{*}$ is in $\mathbf{H I}^{<2}$ but not in $\mathbf{H I}{ }^{<1}$. By Proposition 6.1.15 and by induction, $\mathcal{O}^{*}(n)$ is in $\mathbf{H I}{ }^{<n+1}$ but not in $\mathbf{H I}{ }^{<n}$.

We now describe the reflection functors $\varphi^{<n}: \mathbf{H I} \longrightarrow \mathbf{H I}^{<n}$.
Definition 6.2.12. Let $n$ be a positive integer, and let $\varphi^{<n}(F)$ denote the cokernel of the counit $\epsilon_{F}^{n}: F_{-n}(n) \longrightarrow F$. Since $\epsilon_{F}^{n}$ is natural in $F, \varphi^{<n}$ is a functor.

We will show that $\varphi^{<n}$ is the desired reflection functor from $\mathbf{H I}$ to $\mathbf{H I}{ }^{<n}$. This is established in Proposition 6.2.15. We proceed by first considering the following lemmas: Lemma 6.2.13. The image of HI under $\varphi^{<n}$ is contained in $\mathbf{H I}{ }^{<n}$.

Proof. Let $F$ be an object of HI. We need to verify that $\varphi^{<n}(F)_{-n}=0$. By definition, we have an exact sequence

$$
F_{-n}(n) \longrightarrow F \longrightarrow \varphi^{<n}(F) \longrightarrow 0
$$

Since the functor $F \mapsto F_{-n}$ is exact (see Proposition 3.2.8 and Remark 6.1.13), we then have the following exact sequence

$$
F_{-n}(n)_{-n} \longrightarrow F_{-n} \longrightarrow \varphi^{<n}(F)_{-n} \longrightarrow 0 .
$$

By Proposition 6.1.15, $\left(F_{-n}(n)\right)_{-n} \longrightarrow F_{-n}$ is an isomorphism. Hence, $\varphi^{<n}(F)_{-n}=0$ as desired.

Lemma 6.2.14. The functor $\varphi^{<n}$, restricted to $\mathbf{H I}{ }^{<n}$ is naturally isomorphic to the identity. Consequently, the functor $\varphi^{<n}$ is idempotent (see Definition 2.1.3 (2)), and the image of $\mathbf{H I}$ under $\varphi^{<n}$ is $\mathbf{H I}{ }^{<n}$.

Proof. For each $F$ in $\mathbf{H I}{ }^{<n}$, we have the following exact sequence:

$$
F_{-n}(n) \longrightarrow F \longrightarrow \varphi^{<n}(F) \longrightarrow 0
$$

Since $F \in \mathbf{H I}^{<n}, F_{-n}=0$, and therefore the counit map is 0 . It follows that the natural $\operatorname{map} F \longrightarrow \varphi^{<n}(F)$ is a natural isomorphism as desired. The first statement follows from the fact that $\varphi^{<n}(F)$ is in $\mathbf{H I}{ }^{<n}$, which is established in Lemma 6.2.13.

Proposition 6.2.15. For each $n$, the functor $\varphi^{<n}$ is left adjoint to the inclusion of $\mathbf{H I}{ }^{<n}$ into $\mathbf{H I}$.

Proof. Let $F$ be a homotopy invariant sheaf with transfers, and let $G$ be an object in $\mathbf{H I}^{<n}$. For all $f: F \longrightarrow G$ we have the following commutative diagram:

where $\pi_{F}$ and $\pi_{G}$ are surjections. By Lemma 6.2.14, the map $G \xrightarrow{\pi_{G}} \varphi^{<n}(G)$ is an isomorphism. Define

$$
\chi: \operatorname{Hom}_{\mathbf{H I}}(F, G) \longrightarrow \operatorname{Hom}_{\mathbf{H I}}{ }^{<n}\left(\varphi^{<n}(F), G\right)
$$

by $f \mapsto \pi_{G}^{-1} \circ \varphi^{<n}(f)$. Since $\chi(f) \circ \pi_{F}=f, \chi$ is injective. For $g: \varphi^{<n}(F) \longrightarrow G$, set $f^{\prime}=\pi \circ g$. Since $\chi\left(f^{\prime}\right)=g, \chi$ is a bijection, as desired.

From the way $\chi$ is defined, it is clear that $\chi$ is functorial in both $F$ and $G$. The proposition now follows.

This shows that $\varphi^{<n}$ is an idempotent quotient functor for each natural number $n$. In fact, we have the following result:

Proposition 6.2.16. For each natural number $n, \varphi^{<n}$ is a coradical.

Proof. By Lemma 6.2.14, $\varphi^{<n}$ is idempotent. By Proposition 6.2.15, $\varphi^{<n}$ is a left adjoint, and since $\mathbf{H I}{ }^{<n}$ is an abelian category (see Definition 6.2.11), $\varphi^{<n}$ is therefore right exact. All that remains to show is that for each $F$ in $\mathbf{H I}$,

$$
\varphi^{<n}\left(\operatorname{ker}\left(F \longrightarrow \varphi^{<n}(F)\right)\right)=0
$$

Fix a positive integer $n$, and let $K$ denote the kernel of the surjection $F \longrightarrow \varphi^{<n}(F)$. Since $\varphi^{<n}(F)$ is in $\mathbf{H I}^{<n}$, by definition $\varphi^{<n}(F)_{-n}=0$. Therefore, we have the following commutative diagram with exact rows:

By the Snake Lemma, and using the fact that $\operatorname{cok} \epsilon_{F}=\varphi^{<n}(F)$, we have the exact sequence

$$
0 \longrightarrow \varphi^{<n}(K) \longrightarrow \varphi^{<n}(F) \xrightarrow{q} \varphi^{<n}(F) \longrightarrow 0 .
$$

And the $\operatorname{map} q$ is the identity. It follows that $\varphi^{<n}(K)=0$ as desired.

Since $\varphi^{<n}$ is a coradical, by Theorem 2.2.6, there exists a torsion theory $\left(\mathscr{T}_{n}, \mathscr{F}_{n}\right)$ associated with each $\varphi^{<n}$. We now give another description of the torsionfree subcategories.

Proposition 6.2.17. For each positive integer $n$, the full subcategory $\mathbf{H I}{ }^{<n}$ and the torsionfree subcategory $\mathscr{F}_{n}$ are the same. Hence, the torsionfree subcategories form an ascending strong cofiltration of $\mathbf{H I}$.

Proof. Recall from Lemma 6.2.13 that $\varphi^{<n}(F)_{-n}=0$ for all $F$ in HI. Hence, if $F$ is in $\mathscr{F}_{n}, F_{-n}=\varphi^{<n}(F)_{-n}=0$.

Conversely, if $F_{-n}=0$, then $\varphi^{<n}(F)=F$ by Lemma 6.2.14, and by definition $F$ is an object of $\mathbf{H I}{ }^{<n}$. Hence, the torsionfree subcategory $\mathscr{F}_{n}$ is precisely the full subcategory $\mathbf{H I}{ }^{<n}$ of the sheaves $F$ in $\mathbf{H I}$ for which $F_{-n}=0$. This proves the first claim in the proposition. Since $\mathbf{H I}{ }^{<n}$ form an ascending strong cofiltration, the second claim now follows.

We still have to show that the torsion subcategories $\mathscr{T}_{n}$ form a strong descending filtration. Let us first introduce a more appropriate notation for the torsion subcategory.

Definition 6.2.18. Let $\mathbf{H I}^{\geq n}$ denote the torsion subcategory $\mathscr{T}_{n}$, and $\varphi^{\geq n}$ denote the kernel of the natural surjection id $\longrightarrow \varphi^{<n}$. By Proposition 2.1.8 and Corollary 2.2.7, $\varphi^{\geq n}$ is an idempotent pre-radical, and is right adjoint to the inclusion of $\mathbf{H I}{ }^{\geq n}$ in $\mathbf{H I}$.

We will now show that $\left(\mathbf{H I}^{\geq *}, \varphi^{\geq *}\right)$ defines a descending strong filtration on HI. Lemma 6.2.19. The essential image of $\varphi^{\geq n}$ is $\mathbf{H I}^{\geq n}$, and the restriction of $\varphi^{\geq n}$ to $\mathbf{H I}^{\geq n}$ is the identity.

Proof. Recall from the definition of $\varphi^{\geq n}$ that for each $F$ in HI, there exists a short exact sequence:

$$
0 \longrightarrow \varphi^{\geq n} F \longrightarrow F \longrightarrow \varphi^{<n} F \longrightarrow 0 .
$$

Furthermore, recall from Theorem 2.2.6 that the for all $F$ in $\mathbf{H I}^{\geq n}, \varphi^{<n} F=0$. The lemma now follows.

Lemma 6.2.20. For natural numbers $n$ and $m$ such that $m>n, \varphi^{<m} \varphi^{<n}=\varphi^{<n}$ and there exist a natural isomorphism $\varphi^{<n} \varphi^{<m} \cong \varphi^{<n}$.

Proof. Suppose $F$ is in HI. Since $\mathbf{H I}{ }^{<n}$ is a full subcategory of $\mathbf{H I}{ }^{<m}$, and $\varphi^{<m}$ is the identity on $\mathbf{H I}{ }^{<m}$ (Lemma 6.2.14), we have $\varphi^{<m} \varphi^{<n}=\varphi^{<n}$. It remains for us to show that $\varphi^{<n} \varphi^{<m} \cong \varphi^{<n}$.

We have the following commutative diagram:

where the vertical arrows are the counits. Furthermore, by the same arguments as in the Snake Lemma, we have the "snake tail" exact sequence:

$$
\operatorname{cok} \epsilon_{\sigma^{m}(F)} \longrightarrow \varphi^{<n}(F) \longrightarrow \varphi^{<n} \varphi^{<m}(F) \longrightarrow 0
$$

However, since $\sigma^{m} F \in \mathbf{H I}(m)$, by Proposition 6.1.15 $\epsilon_{\sigma^{m}(F)}$ is an isomorphism. Therefore, the natural map $\varphi^{<n}(F) \stackrel{\cong}{\leftrightarrows} \varphi^{<n} \varphi^{<m}(F)$ is an isomorphism.

Proposition 6.2.22. The collection ( $\mathbf{H I}^{\geq *}, \varphi^{\geq *}$ ) form a descending strong filtration of HI, i.e., we have the following descending tower of subcategories

$$
\mathbf{H I}=\mathbf{H I}^{\geq 0} \supseteq \mathbf{H I}^{\geq 1} \supseteq \cdots \supseteq \mathbf{H I}^{\geq n} \supseteq \mathbf{H I}^{\geq n+1} \supseteq \cdots
$$

and coreflection functors $\varphi^{\geq n}: \mathbf{H I} \longrightarrow \mathbf{H I}^{\geq n}$ such that $\varphi^{\geq n}$ restricted to $\mathbf{H I}{ }^{\geq n}$ is the identity, and $\varphi^{\geq n}(F)$ is a subobject of $F$ for all $n$.

Proof. The only claim left to show is that $\mathbf{H I}^{\geq m} \subseteq \mathbf{H I}^{\geq n}$ for $n \leq m$.
Let $F$ be an object in $\mathbf{H I}^{\geq m}$. Then $\varphi^{<m}(F)=0$, and by Lemma 6.2.20

$$
0=\varphi^{<n} \varphi^{<m}(F)=\varphi^{<n}(F)
$$

Thus, $F$ is in $\mathbf{H I}^{\geq n}$.

We introduce the following notion to describe the strong filtration and cofiltration on HI and its relationship to the coradicals $\varphi^{<*}$.

Definition 6.2.23. We call the strong filtration and cofiltration defined by the torsion theories $\left(\mathbf{H I}^{\geq n}, \mathbf{H I}^{<n}\right)$ for $n=0,1,2, \ldots$ the torsion filtration of $\mathbf{H I}$.

In general, if $\mathscr{A}$ is an abelian category, we say that $\mathscr{A}$ has a torsion filtration if there exists a sequence of idempotent pre-(co)radicals $\varphi^{<*}$ such that the induced torsion theories $\left(\mathscr{A}^{\geq n}, \mathscr{A}^{<n}\right)$ (for $n$ in $\mathbb{Z}$ ) fit together to form a descending strong filtration

$$
\mathscr{A} \supseteq \cdots \supseteq \mathscr{A}^{\geq 0} \supseteq \mathscr{A}^{\geq 1} \supseteq \cdots \supseteq \mathscr{A}^{\geq n} \supseteq \cdots
$$

and an ascending strong cofiltration

$$
0 \subseteq \cdots \subseteq \mathscr{A}^{<0} \subseteq \mathscr{A}^{<1} \subseteq \cdots \subseteq \mathscr{A}^{<n} \subseteq \cdots
$$

We conclude this section by presenting some additional properties of the torsion subcategories and the functor $\varphi^{\geq n}$. Recall from Proposition 6.2.3 that $\sigma^{n} F=F_{-n}(n)$.

Proposition 6.2.24. For all natural numbers $m$ and $n$ such that $m>n$,

1. $\mathbf{H I}^{\geq n}$ is the full subcategory of objects $F$ for which the counit map $\sigma^{n}(F) \longrightarrow F$ is onto.
2. $\mathbf{H I}(n)$ is a proper full subcategory of $\mathbf{H I}{ }^{\geq n}$.
3. there exists a natural isomorphism between $\varphi^{<n} \varphi^{\geq m}$ and $\varphi^{\geq m} \varphi^{<n}$. Furthermore, $\varphi^{\geq n} \varphi^{<m}=\varphi^{<m} \varphi^{\geq n}=0$
4. there exists natural isomorphisms: $\varphi^{\geq n} \varphi^{\geq m} \cong \varphi^{\geq m} \varphi^{\geq n} \cong \varphi^{\geq m}$.

Proof. (1): For all $F$ in $\mathbf{H I}$ and $n \geq 0$, we have the following exact sequence

$$
\sigma^{n}(F) \longrightarrow F \longrightarrow \varphi^{<n}(F) \longrightarrow 0
$$

Therefore, $\varphi^{<n}(F)=0$ if and only if $\sigma^{n}(F) \longrightarrow F$ is a surjection.
(2) : Let $F$ be an object in $\mathbf{H I}(n)$. Then $F \cong F^{\prime}(n)$ for some $F^{\prime}$ in HI. By Proposition 6.1.16, the counit map $\sigma^{n}(F) \longrightarrow F$ is an isomorphism. By part (1), $F \in \mathbf{H I}^{\geq n}$.
(3) : Let $F$ be a homotopy invariant sheaf with transfers. Since $\varphi^{\geq m}(F) \in \mathbf{H I}^{\geq n}$, $\varphi^{<n} \varphi^{\geq m}(F)=0$ by definition. Furthermore, $\varphi^{\geq m} \varphi^{<n}(F)=0$ since it is the kernel of $\varphi^{<m} \varphi^{<n}(F) \longrightarrow \varphi^{<n}(F)$ which is an isomorphism by Lemma 6.2.19.

To show that $\varphi^{<n} \varphi^{\geq m}$ is naturally isomorphic to $\varphi^{\geq m} \varphi^{<n}$, let us first consider the following diagram:

where vertical maps are the counits. Notice that the top row is exact on the right because $\sigma^{m}$ is right exact. Since $m>n$, by Lemma 6.2.13, $\varphi^{<n}(F)$ is in $\mathbf{H I}{ }^{<n}$, which is a subcategory of $\mathbf{H I}{ }^{<m}$ by Proposition 6.2.17. Since $G$ is in $\mathbf{H I}{ }^{<m}$ if and only if $G_{-m}=0$, it follows that $\left(\varphi^{<n}(F)\right)_{-m}=0$. Hence, $\sigma^{m} \varphi^{<n}(F)=0$.

Applying the Snake Lemma to (6.2.25), we obtain the following exact sequence:

$$
\begin{equation*}
0 \longrightarrow \varphi^{<m} \varphi^{\geq n}(F) \longrightarrow \varphi^{<m}(F) \longrightarrow \varphi^{<m} \varphi^{<n}(F) \longrightarrow 0 . \tag{6.2.26}
\end{equation*}
$$

Now $\varphi^{<n} \varphi^{<m}(F) \cong \varphi^{<n}(F)$, and the composition $\varphi^{<m}(F) \longrightarrow \varphi^{<n} \varphi^{<m}(F) \longrightarrow$ $\varphi^{<n}(F)$ is precisely the natural surjection associated to $\varphi^{<n}(F)$. It follows that

$$
\varphi^{<m} \varphi^{\geq n}(F) \cong \varphi^{\geq n} \varphi^{<m}(F)
$$

Since (6.2.25) is natural in $F$, the isomorphism is natural in $F$ as well.
(4): By Proposition 6.2.22, $\mathbf{H I}^{\geq m} \subseteq \mathbf{H I}^{\geq n}$. Since $\varphi^{\geq n}$ restricted to $\mathbf{H I} \mathbf{I}^{\geq n}$ is the identity by Lemma 6.2.19, $\varphi^{\geq n} \varphi^{\geq m}=\varphi^{\geq m}$.

To show that $\varphi^{\geq m} \varphi^{\geq n} \cong \varphi^{\geq m}$, notice that for a given $F$ in HI and positive integer $n$, there exists a commutative diagram

where $\eta$ is the natural surjection id $\longrightarrow \varphi^{<m}$, and the bottom row is precisely the short exact sequence (6.2.26). By Lemma 6.2.20, the map $\varphi^{<n}(F) \longrightarrow \varphi^{<n} \varphi^{<m}(F)$ is an isomorphism. Therefore, by the Snake Lemma, we have $\varphi^{\geq m} \varphi^{\geq n}(F) \cong \varphi^{\geq m}(F)$. Since (6.2.27) is natural in $F$, it follows that the isomorphism $\varphi^{\geq m} \varphi^{\geq n} \longrightarrow \varphi^{\geq m}$ is natural as well.

### 6.3 Slice Filtration on $\mathrm{DM}^{\text {eff,-- }}$ and Torsion Filtration on HI

In this section, we want to relate the filtrations on HI that we have developed with the slice filtration on $\mathbf{D M}{ }^{\text {eff,-- }}$. Recall that the slice filtration structure on $\mathbf{D M}{ }^{\text {eff,-- }}$ is associated with the weak filtration $\left(\mathbf{D M}_{\geq *}^{\text {eff,- }}, \nu \geq *\right)$ and the weak cofiltration $\left(\mathbf{D M}_{<*}^{\text {eff,- }}, \nu^{<*}\right)$ (see Section 5). The main result that we will verify is Proposition 6.3.1. Recall from Definition 6.1.10 that $\tau_{\leq 0} \mathbf{D M}^{\text {eff,- }}$ is the full subcategory of negative objects in $\mathbf{D M}{ }^{\text {eff,- }}$, i.e., the objects $M$ in $\mathbf{D M}^{\text {eff,- }}$ such that $\mathbf{H}^{n} M=0$ for all $n>0$.

Proposition 6.3.1. For each positive integer n, the following diagram of functors commute, with surjective vertical arrows:

The rest of the section will be devoted to the proof of Proposition 6.3.1. First, observe that for every positive integer $n$ and every $M$ in $\tau_{\leq 0} \mathbf{D M}^{\text {eff,- }}$, there exists a slice triangle:

$$
\nu^{\geq n} M \longrightarrow M \longrightarrow \nu^{<n} M \longrightarrow \nu^{\geq n} M[1]
$$

Applying the cohomological functor $\mathbf{H}^{0}$, we obtain the following long exact sequence

$$
\begin{equation*}
\cdots \xrightarrow{\delta_{-1}} \mathbf{H}^{0} \nu^{\geq n}(M) \longrightarrow \mathbf{H}^{0} M \longrightarrow \mathbf{H}^{0} \nu^{<n}(M) \xrightarrow{\delta_{0}} \mathbf{H}^{1} \nu^{\geq n}(M) \longrightarrow \cdots \tag{6.3.2}
\end{equation*}
$$

where $\mathbf{H}^{i} M \stackrel{\text { def }}{=} \mathbf{H}^{0} M[i]$.
Since $\underline{R H o m}_{\mathbf{D M}^{\text {eff },-}}(\mathbb{Z}(n)[n],-)$ is $t$-exact as shown in Lemma 6.1.11, the cochain complex $\underline{\mathrm{RHom}}_{\mathbf{D M}}{ }^{\text {eff,- }}(\mathbb{Z}(n)[n], M)$ is also in $\tau_{\leq 0} \mathbf{D M}^{\text {eff,- }}$. By Proposition 6.1.14,

$$
\begin{aligned}
\mathbf{H}^{0} \nu^{\geq n} M & =\mathbf{H}^{0}\left(\underline{\mathrm{RHom}}_{\mathbf{D M}^{\text {eff },-}}(\mathbb{Z}(n)[n], M) \otimes^{L} \mathbb{Z}(n)[n]\right) \\
& \cong \mathbf{H}^{0}\left(\underline{\mathrm{RHom}}_{\mathbf{D M}^{\mathrm{eff},-},}(\mathbb{Z}(n)[n], M)\right)(n) \\
& =\mathbf{H}^{0}(M)_{-n}(n) \\
& =\sigma^{n} \mathbf{H}^{0} M .
\end{aligned}
$$

This shows that the left square of Proposition 6.3.1 commutes, that $\mathbf{H I}(n)$ is equal to the image of $\tau_{\leq 0} \mathbf{D} \mathbf{M}_{\geq n}^{\text {efff,- }}$ under $\mathbf{H}^{0}$, and the coreflection functors from $\tau_{\leq 0} \mathbf{D M}^{\text {eff,- }}$ to $\mathbf{H I}(n)$ is compatible with $\mathbf{H}^{0}$.

To prove the commutativity of the right square, notice that, for $M$ in $\tau_{\leq 0} \mathbf{D M}^{\text {eff,- }}$, $\mathbf{H}^{0} \nu^{\geq n} M=\left(\mathbf{H}^{0} M\right)_{-n}(n)$. Hence, we get the following exact sequence from (6.3.2)

$$
\left(\left(\mathbf{H}^{0} M\right)_{-n}\right)(n) \longrightarrow \mathbf{H}^{0} M \longrightarrow \mathbf{H}^{0} \nu^{<n}(M) \xrightarrow{\delta_{0}} \mathbf{H}^{1} \nu^{\geq n}(M) .
$$

where the map $\left(\left(\mathbf{H}^{0} M\right)_{-n}(n) \longrightarrow \mathbf{H}^{0} M\right.$ is the counit. If we show that $\mathbf{H}^{1} \nu^{\geq n}(M)=0$, then it is clear that $\mathbf{H}^{0} \nu^{<n}(M) \cong \varphi^{<n}\left(\mathbf{H}^{0} M\right)$. This shows that the right square of Proposition 6.3.1 commutes, completing the proof of Proposition 6.3.1. The vanishing of $\mathbf{H}^{1} \nu^{\geq n}$ is established by the following lemma:

Lemma 6.3.3. For all positive integers $n$ and all $M$ in $\tau_{\leq 0} \mathbf{D M}^{\text {eff,-- }}, \mathbf{H}^{1} \nu^{\geq n}(M)=0$. Proof. Since $\nu^{\geq n} M=\mathbb{Z}(n)[n] \otimes^{L} \underline{R H o m}_{\mathbf{D M}^{\text {eff,-- }}}(\mathbb{Z}(n)[n], M)$, we have already shown in the preceding discussion that $\nu^{\geq n} M$ is a negative object. Therefore, $\mathbf{H}^{1} \nu^{\geq n} M=0$, as desired.

### 6.4 Fundamental Invariants of the Torsion Filtration

As in the case of $\mathbf{D} \mathbf{M}^{\text {eff,-- }}$, we can also define the structure invariants associated to the filtration and cofiltration. In this case, for every natural number $n$, there exists a functorial exact sequence

$$
\sigma^{n} \longrightarrow \sigma^{n-1} \longrightarrow \varphi^{<n} \sigma^{n-1} \longrightarrow 0
$$

Definition 6.4.1. We define $n$-th slice functor on $\mathbf{H I}$ to be the functor $s^{n} \stackrel{\text { def }}{=} \varphi^{<n+1} \sigma^{n}$.
Recall from Definition 5.2 .13 that the $n$-th slice functor of $\left(\mathbf{D M}_{\geq *}^{\text {eff,- }}, \nu \nu^{\geq *}\right)$ is the triangulated endofunctor $\nu^{*}$ that fits into the following exact triangle

$$
\nu^{<n+1} \longrightarrow \nu^{<n} \longrightarrow \nu^{n} \longrightarrow \nu^{<n+1}[1] .
$$

A consequence of Proposition 6.3 .1 is that the slice functors $s^{n}$ on HI agree with the slice functors $\nu^{n}$ on $\mathbf{D M}{ }^{\mathrm{eff},-}$ in the following sense:

Corollary 6.4.2. For all natural numbers $n$, the slice functors satisfy

$$
\mathbf{H}^{0} \nu^{n}=s^{n} .
$$

Proof. Applying $\mathbf{H}^{0}$ to the functorial triangle from (5.2.12), we obtain the following functorial exact sequence in $\mathbf{H I}$ :

$$
\mathbf{H}^{0} \nu^{\geq n+1} \longrightarrow \mathbf{H}^{0} \nu^{\geq n} \longrightarrow \mathbf{H}^{0} \nu^{n} \longrightarrow \mathbf{H}^{1} \nu^{\geq n+1} .
$$

By Proposition 6.1.14, $\mathbf{H}^{0} \nu^{\geq n}=\sigma^{n}$ and $\mathbf{H}^{0} \nu^{\geq n+1}=\sigma^{n+1}$, and by Lemma 6.3.3, $\mathbf{H}^{1} \nu^{\geq n+1}=0$. It follows that $\mathbf{H}^{0} \nu^{n}=s^{n}$ as desired.

Let us first consider the following proposition:
Proposition 6.4.3. For natural numbers $m$ and $n, \sigma^{n} \varphi^{<m}$ is naturally isomorphic to $\varphi^{<m} \sigma^{n}$, and are both 0 if $m \leq n$.

Proof. Let $F$ be an object in HI, and write $L$ for the functor $F \mapsto F(1)$ and $R$ for the functor $F \mapsto F_{-1}$. Since $\sigma^{n}=L^{n} R^{n}$, by Lemma 5.2.5, we have the commutative square

where $f$ is the counit of $\sigma^{m} \sigma^{n}(F) \longrightarrow \sigma^{n}(F)$ and $g$ is obtained by applying $\sigma^{n}$ to the counit $\sigma^{m}(F) \longrightarrow F$. The cokernel of $f$ is precisely $\varphi^{<m} \sigma^{n}(F)$. Since $\sigma^{n}$ is right exact, and the following sequence is exact

$$
\sigma^{m}(F) \longrightarrow F \longrightarrow \varphi^{<m}(F) \longrightarrow 0
$$

the following sequence is also exact.

$$
\sigma^{n} \sigma^{m}(F) \longrightarrow \sigma^{n}(F) \longrightarrow \sigma^{n} \varphi^{<m}(F) \longrightarrow 0 .
$$

It follows that the cokernel of $g$ is $\sigma^{n} \varphi^{<m}(F)$. By the Five Lemma 6.4.3, $\varphi^{<m} \sigma^{n}(F) \cong$ $\sigma^{n} \varphi^{<m}(F)$. Since the square in Lemma 6.2.13 is functorial, it follows that the isomorphism identified above is natural in $F$.

Finally, suppose $m \leq n$. Then by Proposition 6.2.15 $\varphi^{<m}(F)_{-n}=0$. It follows that $\sigma^{n} \varphi^{<m}(F)=0$, and $\varphi^{<m} \sigma^{n}(F)=0$ as well.

Remark 6.4.5. In case the indexing becomes difficult to keep track, one might wish to consider a "bread" analogy. Imagine that a half-infinite loaf of bread is laid out on a line marked from 0 to $\infty$ (representing an $F$ in $\mathbf{H I}$ ), and one is allowed to take cuts at the marked points and subsequently pick up all the bread lying greater than $n$ or less than $n$. For the functors $\varphi^{\geq n}$ and $\sigma^{n}$, the higher the $n$, the less bread one would take. For the functors $\varphi^{<n}$, the greater the $n$, the less bread one would leave.

If one finds the analogy useful, one might wish to interpret Lemma 6.2.20, and Propositions 6.2.24 (3) and (4) with this culinary picture in mind.

As we did for the filtration $\left(\mathbf{H I}(*), \sigma^{*}\right)$ in Definition 6.4.1, we can define the structure invariants for ( $\mathbf{H I}^{\geq *}, \varphi^{\geq *}$ ).

Definition 6.4.6. For each $F$ in $\mathbf{H I}$ and natural number $n$, write $\varphi^{n}$ for the functor $\varphi^{<n+1} \varphi^{\geq n}$, which we define to be the $n$-th fundamental invariant of $F$ associated to $\varphi^{\geq *}$ or simply the $n$-th fundamental invariant.

As it turns out, the $n$-th fundamental invariant is not the same as the $n$-th slice functor on HI. To see this, consider the example introduced in Example 6.2.4. For $\mathcal{O}^{* n}$, from the discussion in loc. cit., we have that

$$
s^{k}\left(\mathcal{O}^{* n}\right)=s^{k}\left(\mathcal{O}^{*}\right)= \begin{cases}\mathcal{O}^{*} & \text { if } k=1 \\ 0 & \text { otherwise }\end{cases}
$$

However, a simple calculation reveals that

$$
\varphi^{k}\left(\mathcal{O}^{* n}\right)= \begin{cases}\mathcal{O}^{* n} & \text { if } k=1 \\ 0 & \text { otherwise }\end{cases}
$$

Nonetheless, the $n$-th slice functor is related to the $n$-th fundamental invariant via the following proposition:

Proposition 6.4.7. Let $m$ and $n$ be natural numbers such that $m>n$. There exists a natural surjection from $\varphi^{<m} \sigma^{n}$ to $\varphi^{<m} \varphi^{\geq n}$. In particular, for each $F$ in $\mathbf{H I}$, there exists a natural surjection $\pi_{m}: s^{m} F \longrightarrow \varphi^{m} F$.

Proof. Let $F$ be an object of HI. We have the following short exact sequence:

$$
0 \longrightarrow \varphi^{\geq n} \varphi^{<m}(F) \longrightarrow \varphi^{<m}(F) \longrightarrow \varphi^{<n} \varphi^{<m}(F) \longrightarrow 0 .
$$

By Lemma 6.2.20, $\varphi^{<m} \varphi^{<n}(F)=\varphi^{<n}(F)$, and therefore $\varphi^{\geq n} \varphi^{<m}(F)$ is the kernel of the surjection $\varphi^{<m}(F) \longrightarrow \varphi^{<n}(F)$. But the sequence

$$
\sigma^{n} \varphi^{<m}(F) \longrightarrow \varphi^{<m}(F) \longrightarrow \varphi^{<n}(F) \longrightarrow 0
$$

is exact. Therefore, the induced map from $\sigma^{n} \varphi^{<m}(F)$ to $\varphi^{\geq n} \varphi^{<m}(F)$ is a surjection as well. Furthermore, since the commutative diagram

is functorial in $F$, the surjection is natural. This establishes the first claim of the proposition, since $\varphi^{\geq n} \varphi^{<m}$ is naturally isomorphic to $\varphi^{<m} \varphi^{\geq n}$ (Proposition 6.2.24 (3)) and $\sigma^{n} \varphi^{<m}$ is naturally isomorphic to $\varphi^{<m} \sigma^{n}$ (Proposition 6.4.3). The second claim follows by setting $n=m-1$.

### 6.5 Weakly Filtered Monoidal Structure on HI

We end this chapter by discussing the tensor properties of the torsion filtration. Let us first consider the following notion:

Definition 6.5.1. Let $(\mathscr{C}, \otimes, \mathbb{1})$ be a monoidal category. We say that $\mathscr{C}$ is a weakly filtered monoidal category if there exists a weak filtration $\left(\mathscr{C}_{*}, \varphi_{*}\right)$ such that for all integers $m$ and $n$ and $C$ in $\mathscr{C}_{m}$ and $C^{\prime}$ in $\mathscr{C}_{n}, C \otimes C^{\prime}$ is in $\mathscr{C}_{n+m}$.

Example 6.5.2. Here are two examples of weakly filtered monoidal categories that we have encountered in this thesis. Recall from Definition 5.3.2 that $\mathbf{D M}_{\geq k}$ is the full subcategory of the objects ( $M, n$ ) in $\mathbf{D M}$ such that $n \geq k$. For $(M, n)$ in $\mathbf{D M}_{\geq k}$ and $\left(M^{\prime}, n^{\prime}\right)$ in $\mathbf{D M}_{\geq l},(M, n) \otimes^{L}\left(M^{\prime}, n^{\prime}\right)$ is equal to $\left(M \otimes M^{\prime}, n+n^{\prime}\right)$, which is an object in $\mathbf{D M}_{\geq k+l}$. Therefore, the triangulated tensor product on $\mathbf{D M}$ is weakly filtered by $\left(\mathbf{D M}_{\geq *}, \nu^{\geq *}\right)$.

Similarly, $\left(\mathbf{H I}(*), \sigma^{*}\right)$ defines a graded symmetric monoidal category on HI under $\otimes^{H}$. To see this, recall from the first paragraph in Section 6.2 that $F$ is in $\mathbf{H I}(n)$ if $F \cong$ $F^{\prime}(n)$. Furthermore, since $F(n)=F \otimes^{H}\left(\mathcal{O}^{*}\right)^{\otimes n}, F(n) \otimes^{H} G(m)=\left(F \otimes^{H} G\right)(n+m)$. Therefore, $\mathbf{H I}(n) \otimes{ }^{H} \mathbf{H I}(m) \subseteq \mathbf{H I}(n+m)$.

We now will show that $\left(\mathbf{H I}^{\geq *}, \varphi^{\geq *}\right)$ defines a weakly filtered monoidal category on HI. We begin by proving the following proposition:

Proposition 6.5.3. For $F$ in $\mathbf{H I}^{\geq n}$ and $G$ in $\mathbf{H I} I^{\geq m}, F \otimes^{H} G$ is an object of $\mathbf{H I} \mathbf{I}^{\geq n+m}$. Proof. Since $\mathbf{H I} \mathbf{z}^{\geq n+m}$ is the torsion subcategory associated to the coradical $\varphi^{<n+m}$, to show that $F \otimes^{H} G$ is in $\mathbf{H I}{ }^{\geq n+m}$, it suffices to show that $\varphi^{<n+m}\left(F \otimes^{H} G\right)=0$. Since $G$ is in $\mathbf{H I}^{\geq n}$, by Proposition 6.2.24(1), the counit $\epsilon: L^{m} R^{m}(G) \longrightarrow G$ is surjective. Since $\otimes^{L}$ is right $t$-exact in both factors, the functor $F \otimes^{H}$ - is right exact by Proposition 6.1.6, and the following map is surjective:

$$
\begin{equation*}
F \otimes^{H} L^{m} R^{m}(G) \xrightarrow{\epsilon_{F} \otimes^{H} G} F \otimes^{H} L^{m} R^{m}(G) \tag{6.5.4}
\end{equation*}
$$

Similarly, we see that the following map is also surjective:

$$
\begin{equation*}
F \otimes^{H} L^{m} R^{m}(G) \xrightarrow{L^{n} R^{n}(F) \otimes^{H} \epsilon_{G}} F \otimes^{H} G . \tag{6.5.5}
\end{equation*}
$$

Composing (6.5.4) and (6.5.5), we obtain a surjection

$$
f: L^{n} R^{n}(F) \otimes^{H} L^{m} R^{m}(G) \longrightarrow F \otimes^{H} G
$$

On the other hand, since $L^{n} R^{n}(F) \otimes^{H} L^{m} R^{m}(G)=L^{n+m}\left(R^{n}(F) \otimes^{H} R^{m}(G)\right)$, the object $L^{n} R^{n}(F) \otimes{ }^{H} L^{m} R^{m}(G)$ is in $\mathbf{H I}(n+m)$, and by Proposition 6.2.24,

$$
\varphi^{<n+m}\left(L^{n} R^{n}(F) \otimes^{H} L^{m} R^{m}(G)\right)=0 .
$$

Since $\varphi^{<n+m}$ is a coradical, which is right exact, the map

$$
\varphi^{<n+m}(f): \varphi^{<n+m}\left(L^{n} R^{n}(F) \otimes^{H} L^{m} R^{m}(G)\right) \longrightarrow \varphi^{<n+m}\left(F \otimes^{H} G\right)
$$

is onto. Therefore, $\varphi^{<n+m}\left(F \otimes^{H} G\right)=0$ and $F \otimes^{H} G$ is an object in $\mathbf{H I}{ }^{\geq n+m}$, as desired.

The following is a direct consequence of Proposition 6.5.3.
Corollary 6.5.6. Let $\otimes^{H}$ be the tensor product on HI defined in Definition 6.1.10. The strong filtration $\left(\mathbf{H I}^{\geq *}, \varphi^{\geq *}\right)$ makes $\left(\mathbf{H I}, \otimes^{H}\right)$ into a weakly filtered monoidal category.

## Chapter 7

## Filtration on CycMod

In this chapter, we will extend the torsion filtration on HI to the Rost-Déglise category of homotopy modules $\mathbf{H I}_{*}$ (see Definition 7.1.1 below). To further simplify notation, in this chapter, let $L: \mathbf{H I} \longrightarrow \mathbf{H I}$ denote the functor $F \mapsto F(1)$, and let $R: \mathbf{H I} \longrightarrow \mathbf{H I}$ denote the functor given by $F \mapsto F_{-1}$. We write $\epsilon^{n}:$ id $\longrightarrow R^{n} L^{n}$ and $\eta^{n}: L^{n} R^{n} \longrightarrow \mathrm{id}$ for the unit and counit maps; we abbreviate $\eta^{1}$ as $\eta$, and $\epsilon^{1}$ as $\epsilon$. The extension of these filtrations to $\mathbf{H I}_{*}$ is new.

### 7.1 Torsion filtration on $\mathbf{H I}_{*}$

Recall from [Dég10, 1.17] the following definition:
Definition 7.1.1. A homotopy module is a $\mathbb{Z}$-graded homotopy invariant sheaf with transfers $F_{*}$ such that for every $n$, there exists a map $s_{n}: F_{n}(1) \longrightarrow F_{n+1}$ such that the corresponding adjunction map $w_{n}: F_{n} \longrightarrow\left(F_{n+1}\right)_{-1}$ is an isomorphism. We call $s_{n}$ and $w_{n}$ the $n$-th suspension and the $n$-th delooping respectively. A morphism $F_{*} \longrightarrow G_{*}$ between homotopy module is a sequence of morphisms $F_{n} \longrightarrow G_{n}$ of homotopy invariant sheaves with transfers that commute with $s_{n}$ and $w_{n}$.

Let $\mathbf{H I}_{*}$ denote the category of homotopy modules. Objects in $\mathbf{H I}_{*}$ will be represented by $\left(F_{*}, w_{*}\right)$ where $F_{*}$ is the $\mathbb{Z}$-graded homotopy invariant sheaf with transfers, and $w_{*}$ is the sequence of deloopings.

There is a fully faithful functor $\sigma^{\infty}: \mathbf{H I} \longrightarrow \mathbf{H I}_{*}$ given by $F \mapsto\left(F_{*}, w_{*}\right)$ where

$$
F_{n}= \begin{cases}F(k) & \text { if } n>0 \\ F & \text { if } n=0 \\ F_{-|n|} & \text { otherwise }\end{cases}
$$

and the $n$-th delooping $F_{n} \longrightarrow\left(F_{n+1}\right)_{-1}$ is the unit map for $n \geq 0$ and the tautological natural isomorphism for $n<0$. Furthermore, $\sigma^{\infty}$ has a right adjoint $\omega^{\infty}: \mathbf{H I}_{*} \longrightarrow \mathbf{H I}$ given by $\left(F_{*}, w_{*}\right) \mapsto F_{0}$ (see [Dég10, 1.18]). Since $\sigma^{\infty}$ is fully faithful and admits a right adjoint, we can regard $\mathbf{H I}$ as a full coreflective subcategory of $\mathbf{H I}_{*}$. The torsion filtration on HI, defined in Definitions 6.2.18 and 6.2.11, gives rise to two $\mathbb{N}$-indexed weak filtrations of $\mathbf{H I}_{*}$. The goal is to extend these filtrations to a $\mathbb{Z}$-indexed strong filtration and a $\mathbb{Z}$-indexed cofiltration of $\mathbf{H I}_{*}$. In particular, we show that there is a sequence of coradicals $\varphi_{*}^{<n}$ on $\mathbf{H I}_{*}$ such that for nonnegative $n$, the restriction of $\varphi_{*}^{<n}$ to HI is $\varphi^{<n}$. In this case, the associated torsion theories will extend the torsion filtrations on $\mathbf{H I}$ to $\mathbf{H I}_{*}$.

The following proposition will be crucial to extending the functors $\varphi^{<n}$ :

Proposition 7.1.2. For $F$ in $\mathbf{H I}$ and all positive numbers $k$ and $n$, there are natural isomorphisms:

$$
\begin{equation*}
L^{k} \varphi^{<n}(F) \cong \varphi^{<n+k} L^{k}(F) \tag{7.1.3}
\end{equation*}
$$

and

$$
\begin{equation*}
R^{k} \varphi^{<n}(F) \cong \varphi^{<n-k} R^{k}(F) . \tag{7.1.4}
\end{equation*}
$$

Proof. By Lemma 5.2.1, the following diagram, natural in $F$, is commutative:

Here, $\epsilon^{n}$ denotes the counit $L^{n} R^{n} \longrightarrow$ id, and the vertical map $L^{n+1} R^{n+1} L(F) \longrightarrow$ $L\left(L^{n} R^{n}(F)\right)$, which is given by the map $L^{n+1} R^{n} \eta^{-1}$, where $\eta$ is the unit id $\longrightarrow R L$, is an isomorphism by Proposition 6.1.15.

The cokernel of $\epsilon^{n+1} L$ is $\varphi^{<n+1} L(F)$. Since $L$ is right exact, the cokernel of $L \epsilon^{n}$ is $L \varphi^{<n}(F)$. By the Five Lemma, it is clear that $\varphi^{<n+1} L(F) \cong L \varphi^{<n}(F)$. Since (7.1.5) is natural in $F$, the isomorphism $\varphi^{<n+1} L \longrightarrow L \varphi^{<n}$ is natural as well. By similar arguments, one can show that $R \varphi^{<n}$ is naturally isomorphic to $\varphi^{<n-1} R$ as well. This proves the proposition for the case $k=1$. The general case follows by induction.

We will now define the coradicals on $\mathbf{H I}_{*}$.
Definition 7.1.6. Let $\left(F_{*}, w_{*}\right)$ be an object of $\mathbf{H I}{ }_{*}$, and write $\varphi_{*}^{<n}(F)$ for the graded homotopy invariant sheaf with transfers where

$$
\left(\varphi_{*}^{<n}(F)\right)_{k} \stackrel{\text { def }}{=} \begin{cases}\varphi^{<n+k}\left(F_{k}\right) & \text { if } n+k>0 \\ 0 & \text { otherwise }\end{cases}
$$

For ease of notation, we will write $\varphi_{k}^{<n}(F)$ for the $k$-th graded component of $\varphi_{*}^{<n}(F)$.
Using the isomorphism $R \varphi^{<n}\left(F_{k}\right) \cong \varphi^{<n-1} R\left(F_{k}\right)$ established in Proposition 7.1.2, let

$$
\varphi_{k}^{<n}(w): \varphi_{k-1}^{<n}(F) \longrightarrow R \varphi_{k}^{<n}(F)
$$

denote the composition

$$
\begin{equation*}
\varphi^{<n+k-1}\left(F_{k-1}\right) \xrightarrow{\varphi^{<n+k-1}\left(w_{k}\right)} \varphi^{<n+k-1} R\left(F_{k}\right) \xrightarrow{\cong} R \varphi^{<n+k}\left(F_{k}\right), \tag{7.1.7}
\end{equation*}
$$

where $w_{k}: F_{k-1} \longrightarrow R\left(F_{k}\right)$ is the $k$-th delooping of $\left(F_{*}, w_{*}\right)$. Since $w_{k}$ is an isomorphism for all $k$, so is $\varphi_{k}^{<n}(w)$. Defining $\varphi_{k}^{<n}(s)$ to be the adjoint of $\varphi_{k}^{<n}(w)$, we immediately have that $\left(\varphi_{*}^{<n}(F), \varphi_{k}^{<n}(w)\right)$ is an object of $\mathbf{H I}$.

Remark. In the discussion above, the map $\varphi_{k}^{<n}(s): L \varphi_{k}^{<n}(F) \longrightarrow \varphi_{k+1}^{<n}(F)$ is actually given by the composition

$$
L \varphi^{<n+k}\left(F_{k}\right) \xrightarrow{\cong} \varphi^{<n+k+1} L\left(F_{k}\right) \xrightarrow{\varphi^{<n+k+1}\left(s_{k}\right)} \varphi^{<n+k+1}\left(F_{k+1}\right),
$$

where $s_{k}: L F_{k} \longrightarrow F_{k+1}$ is $k$-th suspension map. This also follows from Proposition 7.1.2.

Lemma 7.1.8. For each integer $n, \varphi_{*}^{<n}$ is an endofunctor of $\mathbf{H I}_{*}$.

Proof. Let $f_{*}:\left(F_{*}, w_{*}\right) \longrightarrow\left(G_{*}, w_{*}^{\prime}\right)$ be a map between homotopy modules, and let $\varphi_{*}^{<n}(f)$ be a map of graded homotopy invariant sheaves with transfers whose $k$-th graded component is $\varphi_{k}^{<n}(f) \stackrel{\text { def }}{=} \varphi^{<n+k}\left(f_{k}\right)$. If we can show that $\varphi_{*}^{<n}(f)$ is a map in $\mathbf{H I}_{*}$, then it will be clear that $\varphi_{*}^{<n}$ preserves identity maps and compositions.

By naturality of $\rho: R \varphi^{<n+1} \longrightarrow \varphi^{<n} R$ and $\lambda: L \varphi^{<n} \longrightarrow \varphi^{<n+1} L$ and also by the above arguments, the following two squares are commutative

Here, $\varphi_{*}^{<n}(f)$ is a map from $\varphi_{*}^{<n}(F)$ to $\varphi_{*}^{<n}(G)$ as homotopy modules. The fact that $\varphi_{*}^{<n}$ respects composition follows from the functoriality of $\varphi^{<*}$.

We now verify the main result of this section:
Theorem 7.1.9. For each integer $n, \varphi_{*}^{<n}$ is a coradical of $\mathbf{H I}_{*}$.

Proof. $\varphi_{*}^{<n}$ is a quotient functor: certainly $F_{*} \longrightarrow \varphi_{*}^{<n}(F)$ is surjective for each $n$ since it is a surjection at each degree. What we need to verify is that the degree-wise surjection gives rise to a map of homotopy modules. In particular, we need to verify that the following diagram is commutative

To see this, notice that the above diagram is the outer square of the diagram:

Here, the top square commutes by the naturality of id $\longrightarrow \varphi^{<n+k}$, and the bottom square commutes by the definition of the suspension map $s: L \varphi^{<n+k}\left(F_{k}\right) \longrightarrow$ $\varphi^{<n+k+1}\left(F_{k+1}\right)$.

The fact that $\varphi_{*}^{<n}$ respects delooping follows from the duality of the suspension and delooping as established by the preceding lemma.
$\varphi_{*}^{<n}$ is a pre-coradical: The kernel of $F_{*} \longrightarrow \varphi_{*}^{<n}(F)$ is a homotopy module $K_{*}$ whose $k$-th graded term is

$$
\operatorname{ker}\left(F_{k} \longrightarrow \varphi^{<n+k}\left(F_{k}\right)\right)
$$

But $\varphi^{<n}$ is a coradical; hence, $\varphi_{*}^{<n}\left(K_{*}\right)=\varphi^{<n+k}\left(K_{k}\right)=0$. That is $\varphi_{*}^{<n}(K)=0$, as desired.
$\varphi_{*}^{<n}$ is a right exact: since $\varphi^{<n+k}$ is right exact for each $k, \varphi_{k}^{<n}$ is right exact for each associated graded term. It follows that $\varphi_{*}^{<n}$ is right exact.

Recall from Theorem 2.2.6 that if $\varphi$ is a coradical, then the torsion subcategory of $\varphi$ is the full subcategory $\mathscr{T}$ consisting of the objects $T$ such that $\varphi(T)=0$, and the torsionfree subcategory of $\varphi$ is the full subcategory $\mathscr{F}$ whose objects are the objects $F$ such that $\varphi(F)=0$. Furthermore, by Corollary 2.2.7, the inclusion of $\mathscr{F}$ into the ambient category admits a right adjoint given by the kernel of the natural surjection $\mathrm{id} \longrightarrow \varphi$.

Definition 7.1.10. For each integer $i$, let $\mathbf{H I}_{*}^{\geq n}$ and $\mathbf{H I}_{*}^{<n}$ denote the torsion and torsionfree subcategory of $\varphi_{*}^{<n}$ respectively. Let $\varphi_{*}^{\geq n}$ denote the kernel of the natural surjection id $\longrightarrow \varphi_{*}^{<n}$. By the preceding remarks, $\varphi_{*}^{\geq n}$ is right adjoint to the inclusion $\mathbf{H I}_{*}^{\geq n}$ in $\mathbf{H I}_{*}$.

Here is a straightforward consequence of Theorem 2.2.6 and Theorem 7.1.9:
Corollary 7.1.11. An object $\left(F_{*}, w_{*}\right)$ is in $\mathbf{H} \mathbf{I}_{*}^{\geq n}$ if and only if $\varphi_{*}^{\geq n}(F)=\left(F_{*}, w_{*}\right)$.

We now verify the main result of this section.

Corollary 7.1.12. There exists a $\mathbb{Z}$-indexed torsion filtration on $\mathbf{H I}_{*}$. That is, there exists a $\mathbb{Z}$-indexed sequence of coradicals $\varphi_{*}^{<i}$ such that the associated torsion subcategories, which are given by $\mathscr{F}_{i}=\mathbf{H I}_{*}^{<i}$ form an ascending strong cofiltration of $\mathbf{H I}_{*}$ :

$$
\cdots \subseteq \mathbf{H I}_{*}^{<-1} \subseteq \mathbf{H I}_{*}^{<0} \subseteq \mathbf{H I}_{*}^{<1} \subseteq \cdots \subseteq \mathbf{H I}_{*}^{<i} \subseteq \mathbf{H I}_{*}^{<i+1} \subseteq \cdots \subseteq \mathbf{H I}_{*}
$$

and the associated torsionfree subcategories $\mathscr{T}_{i}=\mathbf{H I}_{*}^{\geq i}$ form a descending strong filtration of $\mathbf{H I}_{*}$ :

$$
\cdots \subseteq \mathbf{H I}_{*}^{\geq i} \subseteq \mathbf{H I}_{*}^{\geq i-1} \subseteq \cdots \subseteq \mathbf{H I}_{*}^{\geq 1} \subseteq \mathbf{H I}_{*}^{\geq 0} \subseteq \mathbf{H I}_{*}^{\geq-1} \subseteq \cdots \cdots \subseteq \mathbf{H I}_{*} .
$$

Proof. Since $\left(F_{*}, w_{*}\right)$ is in $\mathbf{H I}$. if and only if $\varphi_{*}^{<n}(F)=\left(F_{*}, w_{*}\right)$ and $\varphi_{*}^{<n}$ is idempotent, the restriction of $\varphi_{*}^{<n}$ to $\mathbf{H I} \mathbf{I}_{*}^{<n}$ is therefore the identity. Similarly, the restriction of $\varphi_{*}^{\geq n}$ to $\mathbf{H I}_{*}^{\geq n}$ is the identity.

What remains to be checked are that $\mathbf{H I}_{*}^{<n} \subset \mathbf{H I}_{*}^{<n+1}$ and $\mathbf{H I}_{*}^{\geq n+1} \subset \mathbf{H I}_{*}^{\geq n}$ for each integer $n$. To proceed, notice that by Lemma 6.2.20, $\varphi^{<n+1} \varphi^{<n}=\varphi^{<n}$. Therefore, for $\left(F_{*}, w_{*}\right)$ in $\mathbf{H I}_{*}^{<n}$, if $\varphi_{*}^{<n}(F)=\left(F_{*}, w_{*}\right)$ then for every $k, \varphi^{<n+k+1}\left(F_{k}\right)=$ $\varphi^{<n+k+1} \varphi^{<n+k}\left(F_{k}\right)=\varphi^{<n+k}\left(F_{k}\right)=F_{k}$. It follows that $\varphi_{k}^{<n+1}(F)=F_{k}$ for all $k$, and $\left(F_{*}, w_{*}\right)$ is in $\mathbf{H I}_{*}^{<n+1}$. Hence, $\mathbf{H I}_{*}^{<n+1} \subset \mathbf{H I}_{*}^{<n+1}$ for every $n$. Using Proposition 6.2.24(4) and Corollary 7.1.12, we can show that $\mathbf{H I}_{*}^{\geq n+1} \subset \mathbf{H I}_{*}^{\geq n}$ for every $n$ by using similar arguments.

Example 7.1.13. Suppose $F$ is a homotopy invariant sheaf with transfers, and let $F_{*}$ denote the image of $F$ under $\sigma^{\infty}$ (see the paragraph after Definition 7.1.1). By Proposition 7.1.2, there are natural isomorphisms in HI:

$$
\varphi^{<n+k}(F(k)) \cong\left(\varphi^{<n} F\right)(k) \text { and } \varphi^{<n}\left(F_{-k}\right) \cong\left(\varphi^{<n+k} F\right)_{-k} .
$$

If $F$ is in $\mathbf{H I}{ }^{<n}$, then $\varphi^{<n} F=F$ by Proposition 6.2.17, and therefore $\varphi_{*}^{<n}\left(F_{*}\right) \cong F_{*}$. Similarly, if $F$ is in $\mathbf{H I}^{\geq n}$, then $\varphi_{*}^{\geq n}\left(F_{*}\right) \cong F_{*}$. It follows that the image of $\mathbf{H I}{ }^{\geq n}$ under $\sigma^{\infty}$ is $\mathbf{H I}_{*}^{\geq n}$ and $\mathbf{H I}{ }^{<n}$ under $\sigma^{\infty}$ is $\mathbf{H I}_{*}^{<n}$ for each positive integer $n$.

The following result show that $\sigma^{\infty}$ relates the coradicals $\varphi^{<n}$ on HI defined in Definition 6.2.12 to the coradicals $\varphi_{*}^{<n}$ on $\mathbf{H I}_{*}$. Recall the notation from the opening paragraph of this chapter that $L$ is the functor $F \mapsto F(1)$, and $R$ is the functor $F \mapsto F_{-1}$.

Proposition 7.1.14. For all integers $n \leq 0, \varphi_{*}^{<n} \sigma^{\infty}=0$. Moreover, for each positive integer $n$, there exists a natural isomorphism $\sigma^{\infty} \varphi^{<n} \xlongequal{\cong} \varphi_{*}^{<n} \sigma^{\infty}$.

Proof. Let $F$ be a homotopy invariant sheaf with transfers, and let $F_{*}=\sigma^{\infty}(F)$. According to the definition of $\sigma^{\infty}$ in the paragraph after Definition 7.1.1,

$$
F_{k}= \begin{cases}L^{k} F & \text { if } k>0 \\ F & \text { if } k=0 \\ R^{|k|} F & \text { if } k<0\end{cases}
$$

First, suppose $n \leq 0$. By Definition 7.1.6, $\varphi_{k}^{<n}(F)=0$ for all $k \leq-n$. We claim that $\varphi_{k}^{<n}\left(F_{*}\right)=\varphi^{<n+k}\left(F_{k}\right)=0$ for all $k>-n$. Notice that $F_{k}=L^{k} F$ is an object in $\mathbf{H I}{ }^{\geq k}$ by Proposition 6.2.24(2). Since $\mathbf{H I}{ }^{\geq k}$ is the torsion subcategory of the coradical $\varphi^{<k}$, $\varphi^{<k}\left(L^{k} F\right)=0$. On the other hand, since $n+k \leq k, \varphi^{<n+k}\left(L^{k} F\right)=\varphi^{<n+k} \varphi^{<k}\left(L^{k} F\right)=$ 0 by Lemma 6.2.20. This proves the first statement in the proposition.

Now suppose that $n>0$. To define a natural isomorphism

$$
\sigma^{\infty}\left(\varphi^{<n} F\right) \xrightarrow{\cong} \varphi_{*}^{<n}\left(\sigma^{\infty} F\right),
$$

we need to define a sequence of natural isomorphisms $\tau_{k}: \sigma^{\infty}\left(\varphi^{<n} F\right)_{k} \longrightarrow \varphi_{k}^{<n}\left(\sigma^{\infty} F\right)$ in HI that is compatible with the delooping maps. That is, for each integer $k$, the following diagram commutes in $\mathbf{H I}$ :

Notice that the $k$-th graded component of $\sigma^{\infty}\left(\varphi^{<n}(F)\right)$ is given by

$$
\sigma^{\infty}\left(\varphi^{<n} F\right)_{k}= \begin{cases}L^{k}\left(\varphi^{<n} F\right) & \text { if } k>0 \\ \varphi^{<n} F & \text { if } k=0 \\ R^{|k|}\left(\varphi^{<n} F\right) & \text { if } k<0\end{cases}
$$

and by definition of $\varphi_{*}^{<n}$,

$$
\varphi_{k}^{<n}(F)= \begin{cases}\varphi^{<n+k}\left(L^{k} F\right) & \text { if } k>0 \\ \varphi^{<n} F & \text { if } k=0 \\ \varphi^{<n+k}\left(R^{|k|} F\right) & \text { if } k<0 \text { and } k>-n \\ 0 & \text { otherwise }\end{cases}
$$

Notice that for $k<0$ and $k+n \leq 0, R^{|k|}\left(\varphi^{<n} F\right)=0$ by Proposition 6.2.13. In this case, $\sigma^{\infty}\left(\varphi^{<n} F\right)_{k}=\varphi_{*}^{<n}\left(\sigma^{\infty} F\right)_{k}=0$, and by setting $\tau_{k}=0$, we obtain natural isomorphisms for all $k<0$ with $k+n \leq 0$.

To complete the proof of the proposition, we need to show that for each $k \geq 0$, there exists a natural isomorphism $\tau_{k}: L^{k} \varphi^{<n} \xrightarrow{\cong} \varphi^{<n+k} L^{k}$ such that the following diagram commutes:

Here, $w_{k}$ is the natural isomorphism given by the unit id $\longrightarrow R L$ and $w_{k}^{\prime}$ is the natural isomorphism corresponding to the $k$-th deloopings of $\varphi_{*}^{<n} \sigma^{\infty}$. We must also show that for each $k<0$ with $n+k>0$, there exists a natural isomorphism $\tau_{k}: \varphi^{<n+k} R^{|k|} \longrightarrow$ $R^{|k|} \varphi^{<n}$ such that the following diagram commutes:

where $w_{k}^{\prime}$ is the natural isomorphism corresponding to the $k$-th delooping of $\varphi_{*}^{<n} \sigma^{\infty}$.
We proceed by first defining the natural isomorphisms $\tau_{k}$. For $k \geq 0$, let $\tau_{k}$ be the natural isomorphism $L^{k} \varphi^{<n} \longrightarrow \varphi^{<n+k} L^{k}$ given by (7.1.3) of Proposition 7.1.2; for $k<0$ and $k+n>0$, let $\tau_{k}$ be the natural isomorphism $R^{|k|} \varphi^{<n} \longrightarrow \varphi^{<n+k} R^{|k|}$ given by (7.1.4). To see that (7.1.15) is commutative for all $k \geq 0$, notice that the inductive step in the proof of Proposition 7.1.2 shows that $R \tau_{k+1}$ factors as the composition

$$
R L^{k+1} \varphi^{<k} \xrightarrow{R L \tau_{k}} R L \varphi^{<n+k} L^{k} \xrightarrow{R \tau^{\prime}} R \varphi^{<n+k+1} L^{k+1},
$$

where $\tau^{\prime}$ is the natural isomorphism given by (7.1.3) for the case $k=1$. In particular, the following diagram is commutative:

By the naturality of the unit transformation, we also have the following commutative square:

Furthermore, notice that $w_{k}^{\prime}$ factors as

$$
\varphi^{<n+k} L^{k} \xrightarrow{\eta \varphi^{<n+k} L^{k}} R L \varphi^{<n+k} L^{k} \xrightarrow{R \tau^{\prime}} R \varphi^{<n+k+1} L^{k+1} .
$$

The commutative squares (7.1.17) and (7.1.18) fit together to give us the square in (7.1.15). We have shown that (7.1.15) is commutative. By similar arguments, (7.1.16) is also commutative. Therefore, the natural isomorphisms $w_{k}$ define a natural isomorphism $\sigma^{\infty} \varphi^{<n} \cong \varphi_{*}^{<n} \sigma^{\infty}$, which proves the second statement of the proposition.

### 7.2 Torsion filtration on cycle modules

We conclude this chapter by showing that there is a torsion filtration structure on the category of cycle modules (defined below). Recall from [Mil70] that for a field $F$, the Milnor $K$-theory of $F$ is the graded commutative ring given by

$$
K_{*}^{M}(F) \stackrel{\text { def }}{=} T^{*}\left(F^{*}\right) / I
$$

where $T^{*}\left(F^{*}\right)$ denotes the tensor algebra of the multiplicative group $F^{*}$, and $I$ denotes the ideal generated by $a \otimes(1-a)$ for all $a$ in $F^{*}$. We define $K_{n}^{M}(F)$ to be 0 for $n<0$ and let $K_{n}^{M}(F)$ be the $n$-th graded piece of $K_{*}^{M}(F)$. We call $K_{n}^{M}(F)$ the $n$-th Milnor $K$-theory of $F$.

Definition 7.2.1 ([Ro96] 1.1). Let $X$ be a finite-type $k$-scheme, and let $\mathcal{F}(k)$ be the category of function fields $E$ of $\mathrm{Sm}_{k}$, i.e., $E$ is the function field of some $k$-scheme $X$ in $\mathrm{Sm}_{k}$, and any morphism $E \longrightarrow E^{\prime}$ in $\mathcal{F}(k)$ is a field homomorphism such that the restriction to $k$ is the identity. A cycle premodule $M$ is a functor which assigns to every field $E$ in $\mathcal{F}(k)$ a $\mathbb{Z}$-graded abelian group $M(E)=\left\{M_{i}\right\}_{i \in \mathbb{Z}}$, together with the following data:

D1. For each field extension $\varphi: E^{\prime} \longrightarrow E$, there is a degree 0 map $\varphi_{*}: M\left(E^{\prime}\right) \longrightarrow$ $M(E)$ called the restriction map associated to $\varphi$

D2. For each finite extension $\varphi: E^{\prime} \longrightarrow E$, there is a degree $0 \mathrm{map} \varphi^{*}: M(E) \longrightarrow$ $M\left(E^{\prime}\right)$ called the corestriction map associated to $\varphi$

D3. For each $E$ in $\mathcal{F}(k)$, the group $M(E)$ is equipped with the structure of a left $K_{*}^{M}(E)$-module, where $K_{*}^{M}(E)$ is the Milnor $K$-ring of $E$.

D4. For a given valuation $v$ of $E$ in $\mathcal{F}(k)$, there exists a map of degree $-1 \partial_{v}: M(E) \longrightarrow$ $M(\kappa(v))$ called the residue map, where $\kappa(v)$ is the residue field of $v$.

The data given in D1-D4 satisfy the following criteria. For a given valuation $v$ of $E$ in $\mathcal{F}(k)$, fix $p$ to be a prime of $v$. The $K_{*}^{M}(E)$-module structure in D3 and the residue map in D4 give rise to a degree preserving map $s_{v}^{p}: M(E) \longrightarrow M(\kappa(v))$ defined by $s_{v}^{p}(\rho)=\partial_{v}(\{p\} \cdot \rho)$, where $\{p\}$ the element in $K_{1}^{M}(E)$ represented by $E$. Following [Ro96, 1.1], we call $s_{v}^{p}$ the specialization map.

R1a. For each field extension $\varphi: E^{\prime} \longrightarrow E$ and field extension $\psi: E \longrightarrow E^{\prime \prime},(\psi \circ \varphi)_{*}=$ $\psi_{*} \circ \varphi_{*}$

R1b. For each finite extension $\varphi: E^{\prime} \longrightarrow E$ and finite extension $\psi: E \longrightarrow E^{\prime \prime}$, $(\psi \circ \varphi)^{*}=\varphi^{*} \circ \psi^{*}$

R1c. For finite extension $\varphi: E^{\prime} \longrightarrow E$ and any field extension $\psi: E^{\prime} \longrightarrow E^{\prime \prime}$ with $\varphi$ finite, define $R=E \otimes_{E^{\prime}} E^{\prime \prime}$, and let $\mathfrak{p}$ be any prime ideal of $R$. (As $R$ is Artin, let $l_{p}$ be the length of the local ring $\left.R_{(\mathfrak{p})}\right)$, and $\varphi_{\mathfrak{p}}: E^{\prime \prime} \longrightarrow R / \mathfrak{p}$ and $\psi_{\mathfrak{p}}: E \longrightarrow R / \mathfrak{p}$
be natural maps.

$$
\psi_{*} \circ \varphi^{*}=\sum_{\mathfrak{p}} l_{p} \cdot\left(\varphi_{\mathfrak{p}}\right)^{*} \circ\left(\psi_{\mathfrak{p}}\right)_{*} .
$$

R2. For any extension $\varphi: E^{\prime} \longrightarrow E, x \in K_{*}^{M}\left(E^{\prime}\right), y \in K_{*}^{M}(E), \rho \in M\left(E^{\prime}\right)$, and $\mu \in M(E)$, then:

R2a. $\varphi_{*}(x \cdot \rho)=\varphi_{*}(x) \cdot \varphi_{*}(\rho)$.

R2b. if $\varphi$ is finite, $\varphi^{*}\left(\varphi_{*}(x) \cdot \mu\right)=x \cdot \varphi^{*}(\mu)$.
R2c. if $\varphi$ is finite, $\varphi^{*}\left(y \cdot \varphi_{*}(\rho)\right)=\varphi^{*}(y) \cdot \rho$.

R3. For any field extension $\varphi: E^{\prime} \longrightarrow E, v$ a valuation on $E$ and $w$ and a valuation on $E^{\prime}$ :

R3a. Suppose $w$ is a nontrivial restriction of $v$ with ramification index $e$. Let $\bar{\varphi}$ : $\kappa(w) \longrightarrow \kappa(v)$ be the induced map. Then:

$$
\partial_{v} \circ \varphi_{*}=e \cdot \bar{\varphi}_{*} \circ \partial_{w} .
$$

R3b. Let $\varphi$ be a finite extension, suppose $w$ is an extension of $v$ to $E$. Let $\varphi_{v}$ : $\kappa(w) \longrightarrow \kappa(v)$ be the induced map on the residue fields. Then

$$
\partial_{v} \circ \varphi^{*} \sum_{v} \circ \partial_{v} .
$$

R3c. Suppose $v$ restricts to a trivial valuation on $E^{\prime}$. Then

$$
\partial_{v} \circ \varphi_{*}=0
$$

R3d. Suppose $v$ restricts to a trivial valuation on $E^{\prime}$. Let $\bar{\varphi}: F \longrightarrow \kappa(v)$ be the induced map on the residue fields. Let $p$ a prime of $v$. Then

$$
s_{v}^{p} \circ \varphi_{*}=\bar{\varphi}_{*}
$$

R3e. Let $u$ be an element of $E$ such that $v(u)=0$. Given $\rho$ in $M(F)$, one has

$$
\partial_{v}(\{u\} \cdot \rho)=-\{\bar{u}\} \cdot \partial_{v}(\rho) .
$$

For $X$ a $k$-scheme, let $X^{(1)}$ denote the collection of codimension 1 subschemes. Let $\xi_{X}$ be the generic point of an irreducible $X$ with $K_{X}=\mathcal{O}_{X}, \xi_{X}$. If $X$ is normal, then for $x$ in $X^{(1)}$, the local ring $\mathcal{O}_{x, X}$ is a valuation ring of $K_{X}$ with residue field $\kappa(x)$. Write $M(x)$ for $M(\kappa(x))$, and $\partial_{x}: M\left(\xi_{X}\right) \longrightarrow M(x)$ for the restriction map.

Furthermore, for $x, y \in X$, let $Z$ be the closed subscheme determined by $x$, and $\bar{Z}$ be the normalization $Z$. Define

$$
\partial_{y}^{x}: M(x) \longrightarrow M(y)
$$

by

$$
\partial_{y}^{x}= \begin{cases}0 & y \notin Z^{(1)} \\ \sum_{z \mid y} \varphi_{\kappa(z), \kappa(x)}^{*} \circ \partial_{z} & \text { otherwise. }\end{cases}
$$

Here, following [Ro96], $z \mid y$ denotes the relation that $z$ lies over $y$. In particular, if $y \in Z^{(1)}$, the sum is taken over all $z$ lying over $y \in Z^{(1)}$. In this case, $\varphi_{\kappa(z), \kappa(y)}^{*}$ is the corestriction map associated to the finite field extension $\kappa(y) \longrightarrow \kappa(z)$.

Definition 7.2.2 ([Ro96] 2.1). A cycle module $M$ on $\mathcal{F}(k)$ is a cycle premodule that satisfies the following conditions:
(FD) Finite support of divisors. $X$ be a normal scheme and $\rho \in M\left(\xi_{X}\right)$. Then $\partial_{x}: M\left(\xi_{X}\right) \longrightarrow M(X)$ is 0 for all but finitely many $x \in X^{(1)}$.
(C) Closedness. If $X$ is an integral local scheme of dimension 2 with closed point $x_{0}$, then the map from $M\left(\xi_{X}\right)$ to $M\left(x_{0}\right)$ given by

$$
\sum_{x \in X^{(1)}} \partial_{x}^{x_{0}} \circ \partial_{\xi}^{x}
$$

is 0 .

Déglise showed in [Dég10] that a homotopy module ( $F_{*}, w_{*}$ ) gives rise to a unique cycle module $\widehat{F_{*}}$, and that this association defines an equivalence between the category of homotopy modules and cycle modules (see [Dég10, 3.7]). Via this categorical equivalence, we obtain the following corollary:

Corollary 7.2.3. There exists a $\mathbb{Z}$-indexed torsion filtration on CycMod. That is, there exists a $\mathbb{Z}$-indexed sequence of coradicals, which by abuse of notation, we also represent by $\varphi_{*}^{<i}$ such that the associated torsion subcategories CycMod ${ }^{<i}$ form an ascending strong cofiltration of CycMod:

$$
\cdots \subseteq \mathbf{C y c M o d}^{<-1} \subseteq \mathbf{C y c M o d}^{<0} \subseteq \cdots \subseteq \mathbf{C y c M o d}^{<i} \subseteq \cdots \subseteq \mathbf{C y c M o d}
$$

and the associated torsionfree subcategories $\mathbf{C y c M o d}{ }^{\geq i}$ form a descending strong filtration of CycMod:
$\cdots \subseteq \mathbf{C y c M o d}^{\geq i} \subseteq \cdots \subseteq$ CycMod $^{\geq 0} \subseteq$ CycMod $^{\geq-1} \subseteq \cdots \cdots \subseteq$ CycMod.

Example 7.2.4. Milnor $K$-theory $K_{*}^{M}$, defined in the paragraph preceding Definition 7.2.1, is an example of a cycle module (see [Ro96, 1.4, 2.5]). By [Dég10, 3.7], the homotopy module corresponding to $K_{*}^{M}$ is $\sigma^{\infty}(\mathbb{Z})$. As we have shown in Example 7.1.13, $\sigma^{\infty}(\mathbb{Z})$ is an object of $\mathbf{H I}_{*}^{\geq 0} \cap \mathbf{H I}_{*}^{<1}$. Hence, $K_{*}^{M} \in \mathbf{C y c M o d}{ }^{\geq 0} \cap \mathbf{C y c M o d}{ }^{<1}$.

## Chapter 8

## Torsion Filtrations on Torsion Monoidal Categories

In this chapter, we generalize the key results proven in the last three chapters by axiomatizing the necessary components to define torsion filtrations on $t$-categories $\mathbf{D}$ with a triangulated tensor structure. Let us begin by defining the following notion:

Definition 8.0.1. Let $(\mathbf{D}, \otimes, \mathbb{1})$ be a tensor monoidal category with a $t$-structure, and let $\mathscr{C}$ be its heart. We say that $\mathbf{D}$ is a torsion monoidal category if $\mathbf{D}$ is equipped with

1. (Partial Internal Hom) a partial internal hom structure (Hom, $\mathbf{D}^{\text {rep }}$ ) (see Definition 4.2.1).
2. (Tate Object) an object $S$ in both $\mathbf{D}^{\text {rep }}$ and the heart of $\mathbf{D}$ called the Tate

such that the following conditions hold:
3. $\mathbb{1}$ is an object of $\mathscr{C}$,

2 . $\otimes$ is right $t$-exact in both factors,
3. (Cancellation) $\underline{\operatorname{Hom}}(S, S \otimes M)=M$,
4. $\operatorname{Hom}(S,-)$ is $t$-exact.

If $\mathbf{D}$ is a torsion monoidal category, we will write $\mathbf{H}^{0}$ for the cohomological functor from $\mathbf{D}$ to its heart. We also write $L: \mathbf{D} \longrightarrow \mathbf{D}$ for the functor sending an object
 Tate object. By assumption, $(L, R)$ is an adjoint pair. Let $L^{n}$ and $R^{n}$ denote the $n$-th iterations of $L$ and $R$ respectively. Since $L$ is left adjoint to $R, L^{n}$ is left adjoint to
$R^{n}$. Furthermore, by the Cancellation axiom (Definition 8.0.1(3)), $R^{n} L^{n}$ is naturally isomorphic to the identity.

Since $\otimes$ is right $t$-exact, it induces a symmetric monoidal and a partial internal hom structure on the heart $\mathscr{C}$ of $\mathbf{D}$, which we represent by $\otimes^{\mathscr{C}}$ and $\underline{\text { Hom}}_{\mathscr{C}}$. The tensor and internal hom bifunctors are given by

$$
C \otimes^{\mathscr{C}} C^{\prime} \stackrel{\text { def }}{=} \mathbf{H}^{0}\left(C \otimes C^{\prime}\right) \quad \text { and } \quad \underline{\operatorname{Hom}}_{\mathscr{C}}\left(C, C^{\prime}\right) \stackrel{\text { def }}{=} \mathbf{H}^{0}\left(\underline{\operatorname{Hom}}\left(C, C^{\prime}\right)\right) .
$$

 representable object of $\mathscr{C}$, i.e., $\operatorname{Hom}_{\mathscr{C}}(S,-)$ is right adjoint to $-\otimes^{\mathscr{C}} S$. We let $L_{H}$ and $R_{H}$ denote the endofunctor on $\mathscr{C}$ given by $F \mapsto F \otimes^{\mathscr{C}} S$ and $F \mapsto \underline{\operatorname{Hom}}_{\mathscr{C}}(S, F)$ respectively. By convention, let $L_{H}^{0}$ and $R_{H}^{0}$ be the identity functor on $\mathscr{C}$, and let $L_{H}^{n}$ and $R_{H}^{n}$ denote the $n$-th iteration of $L_{H}$ and $R_{H}$ respectively. Since $L_{H}$ is left adjoint to $R_{H}, L_{H}^{n}$ is left adjoint to $R_{H}^{n}$ for every integer $n>0$.

Here are some additional results about the functors $L_{H}$ and $R_{H}$ that we will refer to throughout the remainder of this chapter. The following proposition generalizes results from Lemma 6.1.11, Proposition 6.1.14, and Proposition 6.1.15.

Proposition 8.0.2. For all integers $n>0$,

1. $R_{H}^{n}$ is an exact functor,
2. there exists a natural isomorphism between $R^{n}$ and $R_{H}^{n}$ as endofunctors on $\mathbf{H I}$,
3. there exists a natural isomorphism between $\mathbf{H}^{0} L^{n}$ and $L_{H}^{n}$ as endofunctors of $\mathbf{H I}$,
4. there exists a natural isomorphism from id to $R_{H}^{n} L_{H}^{n}$ as endofunctors on $\mathbf{H I}$.

Proof. Since $R$ is $t$-exact, $R_{H}=\mathbf{H}^{0} R$ is exact as an endofunctor on $\mathscr{C}$ by Proposition 6.1.6. Since composition of exact functors is exact, $R_{H}^{n}$ is exact. This proves part (1).

To verify (2), we proceed by induction on $n$. The case $n=1$ follows by definition. Now suppose $\mathbf{H}^{0} R^{n-1}$ is naturally isomorphic to $R_{H}^{n-1}$. Since $R$ is $t$-exact, by [BBD, 1.3.17(ii)], there exists a natural isomorphism between $\mathbf{H}^{0} R$ and $\mathbf{H}^{0} R \mathbf{H}^{0}$. Therefore, we obtain the following chain of natural isomorphisms: $R_{H}^{n} \cong \mathbf{H}^{0} R \mathbf{H}^{0} R^{n-1} \cong \mathbf{H}^{0} R^{n}$.

Since $R$ is $t$-exact, so is $R^{n}$. Furthermore, by definition of $t$-exactness, for all $C$ in $\mathscr{C}$, $R^{n}(C)$ is an object of $\mathscr{C}$. It follows that $\mathbf{H}^{0} R^{n}=R^{n}$.

For (3), since $S$ is in $\mathscr{C}$ and $\otimes$ is right $t$-exact in both factors, $\mathbf{H}^{0} L$ is naturally isomorphic to $\mathbf{H}^{0} L \mathbf{H}^{0}$ as functors on $\mathscr{C}$ by [BBD, 1.3.7(ii)]. Using similar inductive arguments as in (2), we obtain a natural isomorphism between $\mathbf{H}^{0} L^{n}$ and $L_{H}^{n}$.

Since the unit id $\longrightarrow R^{n} L^{n}$ is a natural isomorphism in $\mathbf{D}, \mathbf{H}^{0} \longrightarrow \mathbf{H}^{0} R^{n} L^{n}$ is also a natural isomorphism. Notice that $\mathbf{H}^{0}$ is the identity functor on $\mathscr{C}$ and by part (2) and (3) $\mathbf{H}^{0} R^{n} L^{n}$ is naturally isomorphic to $R_{H}^{n} L_{H}^{n}$. The composition

$$
\mathrm{id} \longrightarrow \mathbf{H}^{0} R^{n} L^{n} \longrightarrow R_{H}^{n} L_{H}^{n}
$$

gives us the desired natural isomorphism, which proves part (4).

### 8.1 Slice filtration of torsion monoidal categories

We begin by constructing the slice filtration on $\mathbf{D}$. This will generalize the results in Section 5.1.

Definition 8.1.1. Let $\mathbf{D}^{<n}$ be the full subcategory of $\mathbf{D}$ consisting of the objects $M$ in $\mathbf{D}$ for which $R^{n} M=0$. Let $\mathbf{D}^{\geq n}$ be the subcategory of objects $M$ such that $M=L^{n}\left(M^{\prime}\right)$ for some $M^{\prime}$ in $\mathbf{D}$. Let $\nu^{\geq n}$ be the functor $L^{n} R^{n}$.

Notice that the arguments in the proof of [HK06, 1.1] rely only on the Cancellation axiom of $\mathbf{D} \mathbf{M}^{\text {eff,- }}$, which is fulfilled by Definition 8.0.1(3) of $\mathbf{D}$. Therefore, the proof of loc. cit. generalizes to show that $\nu^{\geq n}$ is right adjoint to the inclusion of $\mathbf{D}^{\geq n}$ into $\mathbf{D}$.

Let $M$ be an object of $\mathbf{D}$, and let $\eta^{n}: \nu^{\geq n} M \longrightarrow M$ be the counit. Complete $\eta^{n}$ to a triangle:

$$
\nu^{\geq n} M \longrightarrow M \longrightarrow M^{\prime} \longrightarrow \nu^{\geq n} M^{\prime}[1] .
$$

Copying the proof of [HK06, 1.3], we see that $M^{\prime}$ is uniquely determined up to unique isomorphism, and $M \mapsto M^{\prime}$ defines a triangulated endofunctor $\nu^{<n}$ that is left adjoint to the inclusion of $\mathbf{D}^{<n}$ in $\mathbf{D}$. Finally, the discussion in the paragraphs preceding Proposition 5.1.5 can be adapted to this more general setting to show that $\nu^{\geq n}$ restricted to $\mathbf{D}^{\geq n}$ is naturally isomorphic to the identity, and $\nu^{<n}$ restricted to $\mathbf{D}^{<n}$ is also
naturally isomorphic to the identity. We have just verified the following theorem, which is a generalization of Proposition 5.1.5:

Theorem 8.1.2. If $\mathbf{D}$ is a torsion monoidal category, then there exists an $\mathbb{N}$-indexed ascending weak filtration $\left(\mathbf{D}^{<*}, \nu^{<*}\right)$ given by

$$
0=\mathbf{D}^{<0} \subseteq \cdots \subseteq \mathbf{D}^{<n} \subseteq \mathbf{D}^{<n+1} \subseteq \cdots
$$

and a descending weak filtration $\left(\mathbf{D}^{\geq *}, \nu^{\geq *}\right)$ given by

$$
\mathbf{D}=\mathbf{D}^{\geq 0} \supseteq \cdots \supseteq \mathbf{D}^{\geq n} \supseteq \mathbf{D}^{\geq n+1} \supseteq \cdots
$$

It is possible that the weak filtrations are degenerate. However, as the following result shows, the filtration being degenerate is related to the invertibility of $S$. Recall that $S$ is invertible if there exists an object $T$ in $\mathbf{D}$ such that $T \otimes S=\mathbb{1}$.

Proposition 8.1.3. The following are equivalent:

1. the filtration $\left(\mathbf{D}^{<*}, \nu^{<*}\right)$ is trivial, i.e., each $\mathbf{D}^{<n}$ is zero.
2. the filtration $\left(\mathbf{D}^{\geq *}, \nu^{\geq *}\right)$ is degenerate with $\mathbf{D}^{\geq n}=\mathbf{D}$ for all $n$.
3. the Tate object is invertible in $\mathbf{D}$.

Proof. We first show that (1) is equivalent to (2). To see that (1) implies (2), suppose $\mathbf{D}^{<n}=0$ for all $n$. We need to show that every $M$ in $\mathbf{D}$ is isomorphic to $L^{n} M^{\prime}$ for some $M^{\prime}$ in $\mathbf{D}$. However, for every $M$ in $\mathbf{D}$, the following is a distinguished triangle:

$$
\nu^{\geq n} M \longrightarrow M \longrightarrow \nu^{<n} M \longrightarrow \nu^{\geq n} M[1]
$$

where $\nu^{<n} M$ is in $\mathbf{D}^{<n}$. But the assumption that $\mathbf{D}^{<n}=0$ implies that $\nu^{<n} M=0$. Therefore, $L^{n} R^{n} M \cong M$. It follows that $M$ is in $\mathbf{D}^{\geq n}$, and $\mathbf{D}^{\geq n}=\mathbf{D}$ as desired. Conversely, if $\mathbf{D}^{\geq n}=\mathbf{D}$ then for every $M$ in $\mathbf{D}, M \cong L^{n} M^{\prime}$ for some $M^{\prime}$. Suppose $M$ is in $\mathbf{D}^{<n}$, then by definition $0=R^{n} M=R^{n} L^{n} M^{\prime} \cong M^{\prime}$. Therefore, $M=L^{n} 0=0$, and $\mathbf{D}^{<n}=0$.

Now we show that (2) is equivalent to (3). Indeed, if $S$ is invertible with inverse $T$, then $M=S^{\otimes n} \otimes T^{\otimes n} \otimes M=L^{n}\left(T^{n} \otimes M\right)$ which is an object of $\mathbf{D}^{\geq n}$. Conversely,
if $\mathbf{D}^{\geq n}=\mathbf{D}$, then, in particular, $\mathbf{D}^{\geq 1}=\mathbf{D}$. This implies that the unit object $\mathbb{1}$ is an object of $\mathbf{D}^{\geq 1}$. In other words, $\mathbb{1}=T \otimes S$ for some $T$, which shows that $S$ is invertible.

### 8.2 Torsion filtration on the heart

Let us now focus on the heart $\mathscr{C}$ of $\mathbf{D}$. In this section, we will generalize the results developed in Section 6.2 for HI. Recall from Proposition 8.0.2 and preceding paragraphs that the endofunctors $L_{H}^{n}=\mathbf{H}^{0} L^{n}$ and $R_{H}^{n}=\mathbf{H}^{0} R^{n}$ are adjoint. For $F$ in $\mathscr{C}$, let $\varphi^{<n} F$ denote the cokernel of the counit map $L_{H}^{n} R_{H}^{n} F \longrightarrow F$. Since the counit is natural in $F, F \mapsto \varphi^{<n} F$ defines an endofunctor of $\mathscr{C}$. Let $\mathscr{C}^{<n}$ be the full subcategory of all objects $C$ in $\mathscr{C}$ with $\varphi^{<n}(C)=C$, and let $\mathscr{C} \geq n$ be the full subcategory of all objects $C$ in $\mathscr{C}$ with $\varphi^{<n}(C)=0$. The arguments for Theorem 6.2 .10 go through to give us the following result.

Theorem 8.2.1. The functors $\varphi^{<n}, n=1,2 \ldots$, define a sequence of coradicals, whose associated torsion theories $\left(\mathscr{T}_{n}, \mathscr{F}_{n}\right)=\left(\mathscr{C}^{\geq n}, \mathscr{C}^{<n}\right)$ fit together to define a strong ascending cofiltration of $\mathscr{C}$ :

$$
0=\mathscr{C}^{<0} \subseteq \cdots \subseteq \mathscr{C}^{<n} \subseteq \mathscr{C}^{<n+1} \subseteq \cdots
$$

and a strong descending filtration of $\mathscr{C}$ :

$$
\mathscr{C}=\mathscr{C}^{\geq 0} \supseteq \cdots \supseteq \mathscr{C}^{\geq n} \supseteq \mathscr{C}^{\geq n+1} \supseteq \cdots
$$

Following Definition 6.2.18, we define $\varphi^{\geq n}$ to be the kernel of the natural surjection id $\longrightarrow \varphi^{<n}$. By Proposition 2.1.8 and Corollary 2.2.7, $\varphi^{\geq n}$ is an idempotent pre-radical, and is right adjoint to the inclusion of $\mathscr{C} \geq n$ in $\mathscr{C}$. Furthermore, an object $F$ is in $\mathscr{C} \geq n$ if and only if $\varphi^{\geq n} F=F$.

As in the case for HI, we can define $\mathscr{C}(n)$ to be the full subcategory of objects $F$ such that $F \cong L_{H}^{n} F^{\prime}$ for some $F^{\prime}$ in $\mathscr{C}$. As defined, $\mathscr{C}(n) \subseteq \mathscr{C}(m)$ if $n<m$. The arguments of Proposition 6.2 .3 go through to give us the following proposition:

Proposition 8.2.2. The tower of full subcategories

$$
\mathscr{C}=\mathscr{C}(0) \supseteq \cdots \supseteq \mathscr{C}(n-1) \supseteq \mathscr{C}(n) \supseteq \cdots
$$

defines a weak filtration on $\mathscr{C}$.

Drawing on the analogy with HI, the coreflection functor from $\mathscr{C}$ to $\mathscr{C}(n)$ is given by $F \mapsto L_{H}^{n} R_{H}^{n} F$. We also have the following relationship between $\mathscr{C}(n)$ and $\mathscr{C} \geq n$ :

Corollary 8.2.3. For $F$ in $\mathscr{C}(n), \operatorname{Hom}_{\mathscr{C}}(F, G)=0$ for all $G$ in $\mathscr{C}^{<n}$. In particular, $\mathscr{C}(n)$ is a full subcategory of $\mathscr{C} \geq n$.

Proof. If $F$ is an object of $\mathscr{C}(n)$, then $F=L_{H}^{n} F^{\prime}$ for some $F^{\prime}$ in $\mathscr{C}$. Since $R_{H}^{n} G=0$ for all $G$ in $\mathscr{C}^{<n}$,

$$
\operatorname{Hom}_{\mathscr{C}}(F, G)=\operatorname{Hom}_{\mathscr{C}}\left(L_{H}^{n} F^{\prime}, G\right)=\operatorname{Hom}_{\mathscr{C}}\left(F^{\prime}, R_{H}^{n} G\right)=0
$$

for all $G$ in $\mathscr{C}^{<n}$. The first statement of the corollary is now proven. The second statement follows from the definition of $\mathscr{C}^{\geq n}$ as the torsion subcategory of $\mathscr{C}^{<n}$.

The filtrations on $\mathscr{C}$ may also be trivial. Proposition 8.2 .6 and Corollary 8.2.7 below show that, as in the case for $\mathbf{D}$, the degeneracy of the filtrations are related to the the invertibility of $S$. Let us first consider the following lemma. Recall from Definition 8.1.1 that for a given $n, \mathbf{D}^{\geq n}$ is the full subcategory of $\mathbf{D}$ whose objects are the objects $M$ in $\mathbf{D}$ such that $M \cong L^{n} M^{\prime}$ for some $M^{\prime}$ in $\mathbf{D}$, and $\mathbf{D}^{<n}$ is the full subcategory of $\mathbf{D}$ whose objects are the objects $M$ in $\mathbf{D}$ such that $R^{n} M=0$.

Lemma 8.2.4. If $\mathbf{D}^{<n}=0$ then $\mathscr{C}^{<n}=0$.

Proof. Recall from Proposition $8.0 .2(2)$ that $R_{H}^{n}$ is naturally isomorphic to $R^{n}$ on $\mathscr{C}$. Therefore, if $R_{H}^{n} C=0$, then $R^{n} C=0$. Hence, $\mathscr{C}^{<n} \subset \mathbf{D}^{\geq n}$.

If $S$ is invertible in $\mathbf{D}$, then by Proposition $8.1 .3, \mathbf{D}^{<n}=0$ for all $n$, and by the preceding lemma, $\mathscr{C}^{<n}=0$ for all $n$. As we will see in Proposition 8.2.6, $\mathscr{C}^{<n}=0$ for all $n$ implies $\mathscr{C} \geq n=\mathscr{C}$ for all $n$. This shows that if $S$ is invertible in $\mathbf{D}$, then the strong filtration and cofiltration are degenerate. However, the converse does not necessarily hold. Rather, the converse is related to a weaker condition.

Definition 8.2.5. We say that $S$ is $\mathscr{C}$-invertible if there exists some $T$ in $\mathscr{C}$ such that $T \otimes^{\mathscr{C}} S=\mathbb{1}$.

Proposition 8.2.6. The following are equivalent:

1. $\mathscr{C}(*)$ is degenerate with $\mathscr{C}(n)=\mathscr{C}$ for all $n$,
2. $\mathscr{C}^{<*}$ is trivial, for all $n$,
3. $\mathscr{C}^{\geq *}$ is degenerate with $\mathscr{C}^{\geq n}=\mathscr{C}$ for all $n$,
4. $S$ is $\mathscr{C}$-invertible.

Proof. We first show that (1), (2), and (4) are equivalent. The proof that (1) and (4) are equivalent is the same as the proof that (2) and (3) of Proposition 8.1.3 are equivalent. To see that (2) implies (1), let $F$ be an object in $\mathscr{C}$, and let $K$ be the kernel of the counit $L_{H}^{n} R_{H}^{n} F \longrightarrow F$. We have the following exact sequence:

$$
0 \longrightarrow K \longrightarrow L_{H}^{n} R_{H}^{n} F \longrightarrow F \longrightarrow \varphi^{<n} F \longrightarrow 0 .
$$

By Proposition 8.0.2(1), $R_{H}^{n}$ is exact. Applying $R_{H}^{n}$, we obtain the following exact sequence:

$$
0 \longrightarrow R_{H}^{n} K \longrightarrow R_{H}^{n} L_{H}^{n} R_{H}^{n} F \longrightarrow R_{H}^{n} F \longrightarrow R_{H}^{n} \varphi^{<n} F \longrightarrow 0 .
$$

But since $R_{H}^{n} L_{H}^{n} \cong \mathrm{id}, R_{H}^{n} L_{H}^{n} R_{H}^{n} F \longrightarrow R_{H}^{n} F$ is an isomorphism. Therefore, $R_{H}^{n} K=$ $R_{H}^{n} \varphi^{<n} F=0$. That is, $K$ and $\varphi^{<n} F$ are in $\mathscr{C}{ }^{<n}$. It follows that $K=\varphi^{<n} F=0$, and therefore $F=L_{H}^{n} R_{H}^{n} F$. It follows that $\mathscr{C}(n)=\mathscr{C}$.

To show that (4) implies (2), suppose $F$ is in $\mathscr{C}^{<n}$. Then by (4), $F \cong S^{\otimes n} \otimes^{\mathscr{C}} T^{\otimes n}$ for some $T$ in $\mathscr{C}$. Therefore, $L_{H}^{n} R_{H}^{n} F \cong F$. However, this means that $\varphi^{<n} F=0$. By Theorem 2.2.6, $\varphi^{<n} F=F$. Therefore, $F=0$ and $\mathscr{C}^{<n}=0$.

To show that (3) is equivalent to the rest, we first show that (2) implies (3). Suppose $\mathscr{C}^{<n}$ is trivial. Since for all $F, \varphi^{<n} F$ is an object of $\mathscr{C}{ }^{<n}$, it follows that $\varphi^{<n} F=0$. Therefore, $\varphi^{\geq n} F=F$. Thus, $\mathscr{C}^{\geq n}=\mathscr{C}$, as desired.

Finally, to show that (3) implies (2), suppose $\mathscr{C} \geq n=\mathscr{C}$. By Proposition 2.2.3, $\mathscr{C}^{\geq n} \cap \mathscr{C}^{<n}=0$. Hence, $\mathscr{C}^{<n}=0$, as desired.

The following corollary is a direct direct consequence of Lemma 8.2.4 and Proposition 8.2.6.

Corollary 8.2.7. If $S$ is invertible in $\mathbf{D}$, then $S$ is $\mathscr{C}$-invertible.

### 8.3 Slice filtration on the localization of $\mathbf{D}$ by $S$

Next, for a torsion monoidal category $\mathbf{D}$, we can form the localization $\mathbf{D}\left[S^{-1}\right]$ of $\mathbf{D}$ by $S$ (see [MVW, 8 A$]$ ). The objects of $\mathbf{D}\left[S^{-1}\right]$ are pairs $(M, n)$, where $M$ is in $\mathbf{D}$, and $n$ is some integer, and $(M, n+1) \cong(L M, n)$ for all $M$ and $n$. Morphisms between $(M, n)$ and $\left(M^{\prime}, n^{\prime}\right)$ are elements of the direct limit $\underset{\rightarrow}{\lim _{k}} \operatorname{Hom}\left(M(n+k), M^{\prime}\left(n^{\prime}+k\right)\right)$. The relationship between $\mathbf{D}$ and $\mathbf{D}\left[S^{-1}\right]$ is analogous to the relationship between $\mathbf{D M}{ }^{\text {eff,- }}$ and DM. In particular, by the Cancellation axiom (Definition 8.0.1(3)) the localization functor $\Sigma^{\infty}: \mathbf{D} \longrightarrow \mathbf{D}\left[S^{-1}\right]$ which sends an object $M$ in $\mathbf{D}$ to the object $(M, 0)$ is fully faithful. Therefore, we can identify $\mathbf{D}$ as a full subcategory of $\mathbf{D}\left[S^{-1}\right]$.

There is also a tensor product on $\mathbf{D}\left[S^{-1}\right]$, given by

$$
(M, n) \otimes\left(M^{\prime}, n^{\prime}\right)=\left(M \otimes M^{\prime}, n+n^{\prime}\right)
$$

(see [MVW, 8A]). In the case that the cyclic permutation of $(S, 0)^{\otimes 3}$ is the identity in $\mathbf{D}\left[S^{-1}\right]$, by [MVW, $\left.8 \mathrm{~A} .10,8 \mathrm{~A} .11\right]$ the tensor product is a triangulated symmetric tensor on $\mathbf{D}\left[S^{-1}\right]$. In this case, $\mathbf{D}\left[S^{-1}\right]$ is also a torsion monoidal category. However, since $S$ is invertible in $\mathbf{D}\left[S^{-1}\right]$, defining the weak filtrations as we have done in Section 8.1 will result in trivial weak filtrations, as we have shown in Proposition 8.1.3. Nonetheless, we can still construct weak filtrations on $\mathbf{D}\left[S^{-1}\right]$ as follows.

Definition 8.3.1. Let $\mathbf{D}\left[S^{-1}\right] \geq n$ be the full subcategory of $\mathbf{D}\left[S^{-1}\right]$ with objects ( $M, k$ ) such that $(M, k) \cong\left(M^{\prime}, n\right)$ for some $M^{\prime}$ in $\mathbf{D}$. Since $(M, n+1) \cong(L M, n)$, we have the following descending tower of full subcategories:

$$
\mathbf{D}\left[S^{-1}\right] \supseteq \cdots \supseteq \mathbf{D}\left[S^{-1}\right]^{\geq 0} \supseteq \cdots \supseteq \mathbf{D}\left[S^{-1}\right]^{\geq n} \supseteq \mathbf{D}\left[S^{-1}\right]^{\geq n+1} \supseteq \cdots
$$

To show that the nested sequence of subcategories is a descending weak filtration, we need to show that for each integer $n$, there exists a coreflection $\nu^{\geq n}: \mathbf{D}\left[S^{-1}\right] \longrightarrow$ $\mathbf{D}\left[S^{-1}\right]^{\geq n}$. Copying the definition of the functor $\nu^{\geq n}$ on $\mathbf{D M}$ as given in Definition 5.3.4, we define $\nu^{\geq k}$ by setting

$$
\nu^{\geq k}(M, n) \stackrel{\text { def }}{=} \begin{cases}\left(\nu^{\geq k-n} M, n\right) & \text { if } k>n \\ (M, n) & \text { otherwise. }\end{cases}
$$

Copying the proof of Proposition 5.3.6, we see that $\nu^{\geq k}$ is right adjoint to the inclusion of $\mathbf{D}\left[S^{-1}\right]^{\geq k}$ into $\mathbf{D}\left[S^{-1}\right]$. Furthermore, the restriction of $\nu^{\geq k}$ to $\mathbf{D}\left[S^{-1}\right]^{\geq k}$ is the identity. This shows that $\left(\mathbf{D}\left[S^{-1}\right]^{\geq *}, \nu^{\geq *}\right)$ is a descending weak filtration of $\mathbf{D}\left[S^{-1}\right]$.

Remark 8.3.2. Since $(M, 0) \cong\left(M^{\prime}, n\right)$ if and only if $M \cong L^{n} M^{\prime}$, the image of $\mathbf{D}^{\geq n}$ under $\Sigma^{\infty}$ is precisely $\mathbf{D}\left[S^{-1}\right]^{\geq n}$. In particular, we can identify $\mathbf{D}$ with the full subcategory $\mathbf{D}\left[S^{-1}\right] \geq 0$, and the preceding discussion shows that $\nu^{\geq 0}$ is a right adjoint to $\Sigma^{\infty}$.

Next, let $\mathbf{D}\left[S^{-1}\right]^{<n}$ be the full subcategory of objects $(M, k)$ where $\nu^{\geq n}(M, k)=0$. Since $\nu^{\geq k}(M, n)=0$ implies that $\nu^{\geq k+1}(M, n)=0$, we obtain the following ascending tower of full subcategories of $\mathbf{D}\left[S^{-1}\right]$ :

$$
\cdots \subseteq \mathbf{D}\left[S^{-1}\right]^{<0} \subseteq \cdots \subseteq \mathbf{D}\left[S^{-1}\right]^{<n} \subseteq \mathbf{D}\left[S^{-1}\right]^{<n+1} \subseteq \cdots \mathbf{D}\left[S^{-1}\right] .
$$

We want to show that this tower of full subcategories defines a weak filtration of $\mathbf{D}\left[S^{-1}\right]$ by showing that, for each $n$, there exists a reflection $\nu^{<n}: \mathbf{D}\left[S^{-1}\right] \longrightarrow \mathbf{D}\left[S^{-1}\right]^{<n}$. Copying the definition of the functor $\nu^{<k}$ on $\mathbf{D M}$ as given in Definition 5.3.11, we define $\nu^{<k}$ by setting:

$$
\nu^{<k}(M, n)= \begin{cases}\left(\nu^{<n-k} M, n\right) & \text { if } n>k \\ 0 & \text { otherwise }\end{cases}
$$

The arguments for [HK06, 1.3(i)] go through in this general setting to show that for each $k, \nu^{<k}$ is a triangulated functor that is right adjoint to the inclusion of $\mathbf{D}\left[S^{-1}\right]^{<k}$ into $\mathbf{D}\left[S^{-1}\right]$. Moreover, the restriction of $\nu^{<k}$ to $\mathbf{D}\left[S^{-1}\right]^{<k}$ is naturally isomorphic to the identity ( $c f$. Proposition 5.3.12). We have just proved the following theorem, which generalizes the results in Section 5.3.

Theorem 8.3.3. The category of $\mathbf{D}\left[S^{-1}\right]$ is equipped with a descending weak filtration given by $\left(\mathbf{D}\left[S^{-1}\right]^{\geq *}, \varphi^{\geq *}\right)$ and an ascending weak filtration given by $\left(\mathbf{D}\left[S^{-1}\right]^{<*}, \varphi^{<*}\right)$.

The following proposition, which is a consequence of Proposition 8.1.3, relate the degeneracy of the weak filtrations that we defined above with the invertibility of the Tate object $S$.

Proposition 8.3.4. The following are equivalent:

1. the categories $\mathbf{D}\left[S^{-1}\right]^{<n}$ are trivial,
2. the categories $\mathbf{D}\left[S^{-1}\right]^{\geq n}$ is degenerate with $\mathbf{D}\left[S^{-1}\right]^{\geq n}=\mathbf{D}\left[S^{-1}\right]$ for all $n$,
3. $S$ is invertible in $\mathbf{D}$.

Proof. If $S$ is invertible, then $\mathbf{D}\left[S^{-1}\right]$ is equivalent to $\mathbf{D}$. The fact (3) implies (1) and (2) follows directly from Proposition 8.1.3.

To show that (1) implies (2), suppose $\mathbf{D}\left[S^{-1}\right]^{<n}=0$ for all $n$. For any object $(M, k)$ of $\mathbf{D}\left[S^{-1}\right]$ and any integer $n$, we have the following distinguished triangle

$$
\nu^{\geq n}(M, k) \longrightarrow(M, k) \longrightarrow \nu^{<n}(M, k) \longrightarrow \nu^{\geq n}(M, k)[1] .
$$

Notice that $\nu^{<n}(M, k)$ is an object of $\mathbf{D}\left[S^{-1}\right]^{<n}$ and $\nu^{\geq n}(M, k)$ is an object of $\mathbf{D}\left[S^{-1}\right]^{\geq n}$. By the assumption that $\mathbf{D}\left[S^{-1}\right]^{<n}=0$, we see that $(M, k) \cong \nu^{\geq n}(M, k)$, and therefore $(M, k)$ is in $\mathbf{D}\left[S^{-1}\right]^{\geq n}$. Therefore, $\mathbf{D}\left[S^{-1}\right]^{\geq n}=\mathbf{D}\left[S^{-1}\right]$ for all $n$.

To show that (2) implies (3), suppose $\mathbf{D}\left[S^{-1}\right]^{\geq n}=\mathbf{D}\left[S^{-1}\right]$ for all $n$. In particular, $\mathbf{D}\left[S^{-1}\right]^{\geq 1}=\mathbf{D}\left[S^{-1}\right]$. This implies that $(\mathbb{1}, 0)$ is an object of $\mathbf{D}\left[S^{-1}\right]^{\geq 1}$. By definition of $\mathbf{D}\left[S^{-1}\right] \geq 1,(\mathbb{1}, 0) \cong(T, 1)$ for some $T$. Therefore, $\mathbb{1} \cong L T=S \otimes T$, and $S$ is invertible in $\mathbf{D}$.

### 8.4 Torsion Filtration on the Stable Localization of $\mathscr{C}$ by $S$

In this section, we generalize the results of Section 7.1. Copying the construction of $\mathbf{H I}_{*}$, we define the stable localization of $\mathscr{C}$ as follows:

Definition 8.4.1. Let $\mathscr{C}_{S}$ denote the category whose objects are the $\mathbb{Z}$-graded objects $C_{*}$ in $\mathscr{C}$ together with a map $s_{n}: L_{H} C_{n} \longrightarrow C_{n+1}$ for each integer $n$ such that the the corresponding adjunction map $w_{n}: C_{n+1} \longrightarrow R_{H} C_{n}$ is an isomorphism. Following Section 7.1, we call $s_{n}$ the $n$-th suspension map, and $w_{n}$ the $n$-th delooping map. We will represent an object of $\mathscr{C}_{S}$ by $\left(C_{*}, w_{*}\right)$ or simply $C_{*}$ if the collection of delooping maps are clear.

By the Cancellation axiom, $C \mapsto L_{H} C$ is fully faithful, and therefore, the arguments in [Dég10, 1.8] go through for $\mathscr{C}_{S}$ to show that there is a fully faithful functor $\sigma^{\infty}$ from $\mathscr{C}$ to $\mathscr{C}_{S}$ given by $C \mapsto\left(C_{*}, w_{*}\right)$, where the $n$-th graded component of $C_{*}$ is given by

$$
C_{n} \stackrel{\text { def }}{=} \begin{cases}L_{H}^{n} C & \text { if } n>0 \\ C & \text { if } n=0 \\ R_{H}^{|n|} C & \text { otherwise }\end{cases}
$$

and the $n$-th delooping $w_{n}: C_{n} \longrightarrow R_{H}\left(C_{n+1}\right)$ is the unit map for $n \geq 0$ and the identity for $n<0$. As in the case for $\mathbf{H I}_{*}, \sigma^{\infty}$ has a right adjoint $\omega^{\infty}: \mathscr{C} \longrightarrow \mathscr{C}_{S}$, given by $\left(C_{*}, w_{*}\right) \mapsto C_{0}$. Thus, we can view $\mathscr{C}$ as a full coreflective subcategory of $\mathscr{C}_{S}$ whose objects are the $\left(C_{*}, w_{*}\right)$ such that $C_{n}=L_{H}^{n} C_{0}$ for all $n>0$.

Definition 8.4.2. Copying the definition of $\varphi^{<n}$ in Definition 7.1.6, for an object $\left(C_{*}, w_{*}\right)$ of $\mathscr{C}_{S}$, we define $\varphi^{<n}\left(C_{*}\right)$ to be the object in $\mathscr{C}_{S}$ where

$$
\left(\varphi^{<n}\left(C_{*}\right)\right)_{k} \stackrel{\text { def }}{=} \begin{cases}\varphi^{<n+k}\left(C_{k}\right) & \text { if } n+k>0 \\ 0 & \text { otherwise }\end{cases}
$$

For ease of notation, we will write $\varphi_{k}^{<n}\left(C_{*}\right)$ for the $k$-th graded component of $\varphi^{<n}\left(C_{*}\right)$.
As the arguments of Theorem 7.1.9 are entirely formal, replacing $\mathbf{H I}_{*}$ by $\mathscr{C}_{S}$ and $\varphi_{*}^{<k}$ by $\varphi^{<k}$, we obtain the following proposition which is needed in the construction of the strong filtration and cofiltration on $\mathscr{C}_{S}$.

Proposition 8.4.3. For each integer $n, \varphi^{<n}$ is a coradical of the category $\mathscr{C}_{S}$.
We can now define the full subcategories in the strong filtration and cofiltration of $\mathscr{C}_{S}$. Recall from Theorem 2.2.6 that if $\varphi$ is a coradical, then the torsion subcategory of $\varphi$ is the full subcategory $\mathscr{T}$ consisting of the objects $T$ such that $\varphi(T)=0$, and the torsionfree subcategory of $\varphi$ is the full subcategory $\mathscr{F}$ whose objects are the objects $F$ such that the natural map $F \longrightarrow \varphi(F)$ is an isomorphism.

Definition 8.4.4. Let $\mathscr{C}_{S}^{<n}$ be the torsionfree subcategory of $\varphi^{<n}$, i.e., $C_{*}$ is an object of $\mathscr{C}_{S}^{<n}$ if and only if $\varphi^{<n}\left(C_{*}\right)=C_{*}$. Let $\mathscr{C}_{S}^{\geq n}$ be the torsion subcategory of $\varphi^{<n}$. The objects of $\mathscr{C}_{\bar{S}}^{\geq n}$ are the $C_{*}$ in $\mathscr{C}_{S}$ such that $\varphi^{<n}\left(C_{*}\right)=0$.

Copying the proof for Corollary 7.1.12 we obtain the following theorem.
Theorem 8.4.5. The sequence of functors $\varphi^{<n}, n=\ldots,-1,0,1, \ldots$ on $\mathscr{C}_{S}$ is a $\mathbb{Z}$ indexed sequence of coradicals whose associated torsion theories

$$
\left(\mathscr{T}_{n}, \mathscr{F}_{n}\right)=\left(\mathscr{C}_{S}^{\geq n}, \mathscr{C}_{S}^{<n}\right)
$$

define an ascending strong cofiltration

$$
\cdots \subseteq \mathscr{C}_{S}^{<0} \subseteq \cdots \subseteq \mathscr{C}_{S}^{<n} \subseteq \mathscr{C}_{S}^{<n+1} \subseteq \cdots
$$

and a strong descending filtration

$$
\mathscr{C}_{S} \supseteq \cdots \supseteq \mathscr{C}_{S}^{\geq 0} \supseteq \cdots \supseteq \mathscr{C}_{S}^{\geq n} \supseteq \mathscr{C}_{\bar{S}}^{\geq n+1} \supseteq \cdots
$$

on $\mathscr{C}_{S}$.
The following proposition shows that $S$ is $\mathscr{C}$-invertible if and only if each of the weak filtrations above are degenerate:

Proposition 8.4.6. The following are equivalent:

1. $\mathscr{C}_{S}^{<*}$ is trivial, for all $n$,
2. $\mathscr{C}_{\bar{S}}^{\geq *}$ is degenerate with $\mathscr{C}_{\bar{S}}^{\geq n}=\mathscr{C}$ for all $n$,
3. $S$ is $\mathscr{C}$-invertible.

Proof. To see that (1) implies (2), suppose $\mathscr{C}_{S}^{<n}=0$ for all integers $n$. Then $\varphi^{<n}\left(C_{*}\right)=$ 0 for all $C_{*}$ in $\mathscr{C}_{S}$, and therefore $\varphi^{<n}=0$ for all $n$. Since $C_{*}$ is in $\mathscr{C}_{\bar{S}}^{\geq n}$ if and only if $\varphi^{<n}\left(C_{*}\right)=0$ (see Definition 8.4.4), it follows that $\mathscr{C}_{S}^{\geq n}=\mathscr{C}_{S}$ for all $n$.

Now, assume $\mathscr{C}_{S}^{\geq n}=\mathscr{C}_{S}$ for all $n$. By Proposition 2.2.3, $\mathscr{C}_{S}^{<n} \cap \mathscr{C}_{S}^{\geq n}=0$. Hence, $\mathscr{C}_{S}^{<n}=0$ for all $n$. This shows that (2) implies (1).

To show that (1) implies (3), suppose $\mathscr{C}_{S}^{<n}=0$ for all $n$. As we have shown in the proof of (1) implies (2), $\varphi^{<n}=0$ as an endofunctor on $\mathscr{C}_{S}$ for all $n$, which further implies that $\varphi^{<n}=0$ as an endofunctor on $\mathscr{C}$ for all $n>0$. This implies that $\mathscr{C}^{<n}=0$ for all $n$, and by Proposition 8.2.3, $S$ is invertible in $\mathscr{C}$.

To see that (3) implies (1), suppose $S$ is invertible in $\mathscr{C}$. Then by Proposition 8.2.3, $\mathscr{C}^{<n}=0$ for all $n$. Therefore, $\varphi^{<n}(C)=0$ for all $C$ in $\mathscr{C}$ and $n>0$. Hence, $\varphi^{<n}\left(C_{*}\right)=0$ for all $C_{*}$ in $\mathscr{C}_{S}$ and integer $n$. It follows that the torsionfree categories are trivial, i.e., $\mathscr{C}_{S}^{<n}=0$ for all integer $n$.
