# ABSTRACT OF THE DISSERTATION <br> ACTIVATION OF SMALL MOLECULES BY PINCER IRIDIUM CATALYSTS 

By

## KATHLEEN DONOHUE FIELD

## Dissertation Director:

## Alan S. Goldman

Since the initial report of pincer complexes in the late 1960 's, much research has been undertaken to understand the reactivity and applicability of these complexes. This thesis aims to add to the rich knowledge of pincer complexes and the activation of small molecules to lead to interesting chemical transformations.

Advantageously, the pincer framework can be easily adapted by changing different aspects of the ligand. The synthesis, characterization and reactivity of $(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrH}_{\mathrm{n}}$, in which the para position on the backbone of the catalyst has been changed from a hydrogen to a methyl group is reported. Finally, attempts to isolate the highly reactive 3-coordinate 14-electron (Me-PCP)Ir species are also addressed.

Rather than isolation or observance of any active catalytic species proposed as a $14 \mathrm{e}^{-}$, agostic, solvated, or dimeric species, it has been found that the cyclometalation or C-H activation of the 'butyl group attached to one of the phosphorous atoms occurs readily. Characterization of cyclometalated complexes and an interesting cyclometalated insertion product is described. Two different mechanisms are proposed and discussed in relation to previously cited pathways for the formation of each complex.

The knowledge of the activation and binding of oxygen as well as the reactivity of oxidants and isolation of reactive intermediates is limited. The synthesis and characterization of two (Me-PCP)Ir oxygen species is detailed via reaction with oxygen directly followed by a discussion of the reactivity with other oxidants.

A combined experimental and computational study was completed to determine the binding energies for the addition of a variety of ligands to the metal center of (PCP) IrHCl, (PCP) IrH ${ }_{2}$, and the
(PCP)Ir fragment. The thermodynamics were determined directly through equilibrium reactions and compared to values derived from DFT calculations utilizing a variety of functionals with good agreement.

Finally, the activation of hydrazine and related compounds by the parent (PCP) $\mathrm{IrH}_{2}$ complex is achieved and leads to both dehydrogenation and hydrogenation of hydrazine by pincer iridium (PCP) type catalysts to synthesize $\mathrm{N}_{2}, \mathrm{H}_{2}$ and $\mathrm{NH}_{3}$. The reactivity of other pincer complexes for this reaction will be compared and a computationally calculated mechanism for both pathways will be discussed along with supporting experimental evidence.

## Dedication

To my parents, Joan and Bill, my sister Jenny, and my fiancé Joe, you inspire and guide me every day.

## Acknowledgements

I would like to thank my advisor Professor Alan Goldman. He has allowed me to pursue challenging projects and grow as a scientist over the last six years; I have truly enjoyed working with him.

I would like to thank Professor Karsten Krogh-Jespersen for not only serving on my committee, but also for his collaboration. His expertise proved invaluable for many of my projects, but mostly for our work on the thermodynamic study of ligand binding energies.

I would like to thank Professor Kai Hultzsch for his valuable time and serving on my committee. His class provided a deep foundation in the area of organometallic chemistry for which I am ever thankful.

Dr. Carolyn Supplee is thanked for not only serving as my committee member but for also introducing me to my love of organometallic chemistry. Carolyn has not only been an excellent mentor and professor during my undergraduate years, she has also become a caring friend over the last six years.

I express gratitude to Dr. Nagarajan Murali for assistance with NMR spectroscopy and Dr. Tom Emge for his work with X-Ray crystallography.

I would like to thank all former and current members of the Goldman Research group. I would like to thank Drs. Jongwook Choi and Agnieszka Nawara-Hultzsch for their support and advice as I started my research here at Rutgers. I would like to thank Dr. Sabuj Kundu for his advice and the work he contributed towards the thermodynamic study. Tian Zhou was responsible for the computational component of my experimental work with hydrazine and I thank him for his contributions. Dr. Yury Kissin has not only been a valued advisor for the entire Goldman group, but I have had the pleasure of working with him while analyzing my kinetics data for hydrazine. I am very grateful for all of his assistance. Samreen Bano and Milos Cejkovmich are acknowledged for their dedicated time and effort in helping me with various experiments. I would like to thank Mike Haibach, Dr. Jason Hackenberg, and Dr. David Wang for all the discussions we have had over the years and I would like to thank Dr. David Laviska for his friendship and leadership during my time here at Rutgers.

I am grateful for my professors at Monmouth University whom fostered my knowledge of chemistry and inspired me to pursue my doctoral degree. I am also thankful for all the teachers who enabled my love of knowledge.

Finally, I would like to thanks all my friends and family who supported me not only during my pursuit of a doctoral degree, but throughout different periods of my life. Words cannot express my gratitude and love to my parents Joan and Bill and sister Jenny who supported me in all my endeavors. To Joe, thank you for keeping the smile on my face. This would not have been possible without each of you.

Ammonia Production for the Catalytic Reduction of Hydrazine with Varied Catalytic Conditions

## Chapter 1

## Introduction

The activation of small molecules by transition metals leads to knowledge of bond reactivity, which can then be applied to functionalization for synthesis of new materials. In general, the activation of small molecules proceeds through oxidative addition. Oxidative addition and the reverse process, reductive elimination, are fundamental reaction steps in many organometallic reactions and catalytic cycles. ${ }^{1,2}$ Oxidative addition implies a formal two electron addition to a metal center involving the cleavage of an XY bond and formation of $\mathrm{M}-\mathrm{X}$ and $\mathrm{M}-\mathrm{Y}$ bonds.

Diatomic hydrogen as the smallest molecule has a rich chemistry associated with transition metals. ${ }^{3}$ One of the first examples of $\mathrm{H}_{2}$ addition to an iridium center was reported by Vaska in 1962 (Scheme 1.1). ${ }^{4}$ The unsaturated $16 \mathrm{e}^{-}$complex can oxidatively add $\mathrm{H}_{2}$ easily to give an $18 \mathrm{e}^{-}$iridium hydride species. The release of $\mathrm{H}_{2}$ from the coordinatively saturated center to regenerate the $16 \mathrm{e}^{-}$species is the reductive elimination. Following, Vaska successfully reported the hydrogenation of ethylene and acetylene using this $18 \mathrm{e}^{-}$complex. ${ }^{5}$

## Scheme 1.1 Oxidative Addition of $\mathrm{H}_{2}$ to Vaska's Complex

Wilkinson reports the oxidative addition of hydrogen to a square planar rhodium complex during the catalytic hydrogenation of alkenes to form alkanes (Figure 1.1). ${ }^{6,7}$ After release of one triphenylphosphine ligand $\left(\mathrm{PPh}_{3}\right)$, the active species is generated and can undergo oxidative addition of hydrogen easily to give the dihydride complex. Addition of an olefin gives the $\pi$ complex which then undergoes hydride migration to give the olefin insertion product. The final step is reductive elimination of the alkane to regenerate the active species.

Figure 1.1 Mechanism for the Hydrogenation of Alkenes via Wilkinson's Catalyst

The oxidative addition of $\mathrm{H}_{2}$ has been studied in great detail as it is not only an intermediate step in hydrogenation and hydroformylation reactions but the activation of $\mathrm{H}_{2}$ also provides information regarding the activation of other bonds. $\mathrm{C}-\mathrm{H}$ activation, similar in nature to the oxidative addition of $\mathrm{H}_{2}$ to transition metals probably represents the most desired reactions in chemistry as it can lead to functionalization forming a wide variety of organic molecules. ${ }^{8}$ The first report of C-H activation was published in 1965 by Chatt and Davidson in which a ruthenium catalyst activates the aryl hydrogen bonds of naphthalene to give a ruthenium aryl hydride complex. ${ }^{9,10}$ Similarly, Green and coworkers reported the addition of benzene upon photolytic loss of $\mathrm{H}_{2}$ from $\mathrm{Cp}_{2} \mathrm{WH}_{2}$ (Scheme 1.2). ${ }^{11-13}$

Scheme 1.2 Oxidative Addition of Benzene to $\mathrm{Cp}_{2} \mathrm{WH}_{2}$

In the early 1980's the first reports for the C-H activation of alkanes appeared as Bergman, ${ }^{14,15}$ Jones, ${ }^{16}$ and Graham ${ }^{17}$ each reported the oxidative addition of C-H bonds of alkanes to transition metal complexes. Surprisingly, there is high selectivity to activate the strongest primary C-H bond rather than the tertiary C-H bond. ${ }^{18-20}$ Separate reports have also examined the kinetic and thermodynamic favorability for the C-H activation of arene C-H bonds over alkyl C-H bonds, even though arene C-H bonds are much stronger than alkyl C-H bonds. One reason is the difference between metal-aryl and metal-alkyl bond strengths versus the bond strengths of the starting molecules. ${ }^{18,21,22}$

The oxidative addition of C-H bonds is highly important in many transformations. The direct production of alkenes from abundant alkanes is very desirable as olefins are highly useful precursors for many chemical transformations. The first selective homogeneous dehydrogenation of alkanes was studied by Crabtree in 1979, in which a cationic $\left.\left[\mathrm{IrH}_{2} \text { (acetone }\right)_{2}\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{BF}_{4}\right]$ complex dehydrogenated cyclopentane or cyclooctane in the presence of tert-butylethylene (TBE), the hydrogen acceptor. ${ }^{23}$ Soon after, catalytic transfer dehydrogenations were reported (Equation 1). ${ }^{24-26}$

Shilov reported the reverse process, the hydrogenation of olefins using platinum catalysts. ${ }^{10}$ The critical step in this reaction was reversible C-H activation to give a $\operatorname{Pt}$ (alkyl) species. Later in 1972, Shilov reported the conversion of methane to methanol via a $\mathrm{Pt}(\mathrm{II}) / \mathrm{Pt}(\mathrm{IV})$ system. ${ }^{27}$ This was the first example of alkane functionalization and despite the use of stoichiometric $\operatorname{Pt}(\mathrm{IV})$ as the oxidant in this system, it still remains one of the few examples of methane conversion to methanol.

Alkane metathesis has been defined as the molecular redistribution of alkanes and has proven most promising in the area of Fischer Tropsch (FT) chemistry. ${ }^{28,29}$ In FT chemistry, high molecular weight (MW) $n$-alkanes are cracked to lower MW alkanes generating highly useful C9-C19 fragments or diesel fuel and less desirable C3-C8 fragments. Alkane metathesis allows for conversion of the C3-C8 fragments back into the useful diesel fraction (Figure 1.2). The first example of alkane metathesis was achieved by Burnett and Hughes in 1973 with a combination of two heterogeneous catalysts. ${ }^{30}$ In this process, platinum/alumina acted as the transfer dehydrogenation catalyst while tungsten oxide/silica acted as the olefin metathesis catalyst.

Figure 1.2 General Reaction Scheme for Alkane Metathesis

One of the most successful catalysts for dehydrogenation and alkane metathesis has been the pincer complex. The PCP ligand (where $\mathrm{PCP}=\kappa^{3}-\mathrm{C}_{6} \mathrm{H}_{6}-2,6-\left(\mathrm{CH}_{2} \mathrm{PR}_{2}\right)_{2} ; \mathrm{R}={ }^{t} \mathrm{Bu}$ ) and first pincer complex were synthesized by Shaw in 1976 (Figure 1.3), however the term "pincer" was coined by van Koten much later. ${ }^{31-34}$ Generally, the nomenclature abbreviation for these complexes stems from the atoms attached to the metal center, and additional denotations are only to differentiate any changes from the parent PCP complex. The wide applicability of these complexes is due in part to their high stability at a variety of temperatures as well as their extensive tunability. Adaptations to the sterics, electronics and reactivity of the pincer complex can be achieved by making subtle changes to the R-groups attached to the phosphorous atoms, ${ }^{35-37}$ replacing the phosphorous atoms with nitrogen atoms, ${ }^{38}$ exchanging the methylene linkers with oxygen $^{39}$ atoms, making changes to the backbone aryl ring and introducing different transition metals including Ir , Rh, Ni, Pt, and Pd. ${ }^{40-50}$

Figure 1.3 General Structure of Pincer Complex

Pincer complexes have achieved much attention due to their high applicability in a variety of reactions (Figure 1.4). ${ }^{43}$ In 1996, Kaska and Jensen reported the first transfer dehydrogenation utilizing
pincer complexes. ${ }^{51-53}$ Interestingly, the iridium pincer complex showed high activity for the cyclooctane/TBE transfer dehydrogenation while its rhodium counterpart was ineffective. The acceptorless dehydrogenation utilizing pincer complexes was also demonstrated. In 2006, Goldman and Brookhart reported the use of a pincer catalyst as the transfer dehydrogenation catalyst in combination with a Schrock molybdenum olefin metathesis catalyst for alkane metathesis. ${ }^{28}$ In addition to the dehydrogenation of alkanes, the dehydrogenation of other substrates has been reported including cycloalkanes followed by a subsequent report by Goldman et. al. describing the C-H activation of aryl and vinyl substrates. ${ }^{52,54,55}$ There have been reports on the use of pincer catalysts for C-C bond forming reactions including Suzuki biaryl and Heck olefin arylation coupling reactions with success. ${ }^{34}$

Pincer complexes can successfully activate O-H bonds, including water ${ }^{56}$ and C-O type bonds. ${ }^{57}$ The oxidative addition of oxygen leads to differing results, for instance, insertion of $\mathrm{O}_{2}$ into a Pd- H bond of $(\mathrm{PCP}) \mathrm{PdH}$ yields a $\mathrm{Pd}(\mathrm{II})$ hydroperoxide complex, while reaction of the $(\mathrm{PCP}) \mathrm{Ir}$ fragment with $\mathrm{O}_{2}$ leads to the mono and bis di-oxygen complexes and no evidence of oxygen insertion. ${ }^{58-60}$ The dehydrogenation of alcohols to give aldehydes and ketones as well as the activation of esters and ethers, has also been published. ${ }^{61,62}$ Recently, the addition of olefins across alcohols through hydroaryloxylation was developed. ${ }^{63}$ Even the oxidative addition of C-F bonds via initial C-H activation has also been reported. ${ }^{64}$

Given, that $\mathrm{N}-\mathrm{H}$ bonds and $\mathrm{C}-\mathrm{H}$ bonds are intrinsically similar in homolytic bond strengths and the importance of bond activation of both types in hydroamination, transitioning from C-H activation to $\mathrm{N}-\mathrm{H}$ activation seems only natural. The dehydrogenation of tertiary amines to give enamines, as well as the activation of other N-H bonds, has been reported with pincer catalysts. ${ }^{62,65-67}$ The hydrogenation of amides to give amines and alcohols was also reported by Milstein using a (PNP)Ru catalyst. ${ }^{68}$ In 2006, Goldberg and Heinekey reported the dehydrogenation of ammonia-borane occurring through a boron bound hydride intermediate rather than via $\mathrm{N}-\mathrm{H}$ activation. ${ }^{69,70}$ Unfortunately, the coordination of $\mathrm{N}_{2}$ was found as an inhibitory reaction throughout many reactions depicted for pincer complexes. ${ }^{71-73}$ Overall the reactions described are a sample of the high applicability and reactivity of pincer complexes.

Figure 1.4 Activation of Small Molecules by Pincer Iridium Complexes

### 1.2 Research Goals of This Thesis

This thesis aims to add to the wealth of knowledge in the area of small molecule activation via pincer iridium catalysts. The first portion of the thesis focuses on the synthesis and reactivity of a new pincer complex [(Me-PCP)Ir] in which the para position hydrogen of the aryl backbone has been replaced with a methyl group. The second portion of this thesis focuses on studies with the parent (PCP)Ir complex. The two portions of the thesis are tied together by the discussions of the active $14 \mathrm{e}^{-}$fragment.

Chapter 2 will discuss the synthesis of (Me-PCP) $\mathrm{IrH}_{2}$, in which the hydrogen in the para position of the parent ( PCP ) $\mathrm{IrH}_{2}$ complex has been replaced with a methyl group along with a discussion of its reactivity with small molecules (i.e. $\mathrm{N}_{2}, \mathrm{CO}$, ethylene, etc.). Comparisons will be made between the parent $(\mathrm{PCP}) \mathrm{IrH}_{2}$ and derivatized (Me-PCP) $\mathrm{IrH}_{2}$ complexes. Finally, attempts to isolate the active $14 \mathrm{e}^{-}(\mathrm{Me}-$ PCP)Ir species will be discussed.

Chapter 3 presents the synthesis of cyclometalated complexes in which the ( $\mathrm{R}-\mathrm{PCP}$ ) $\operatorname{Ir}(\mathrm{R}=\mathrm{H}$ and Me ) complexes undergo intramolecular $\mathrm{C}-\mathrm{H}$ activation of the tert-butyl group rather than isolation or observance of any proposed $14 \mathrm{e}^{-}$, agostic, solvated, or dimeric species. Addition of CO to the cyclometalated complexes leads to an interesting insertion product in which a carbon is inserted between the backbone and iridium metal center. The characterization and proposed mechanisms are discussed in relation to previously cited pathways for the formation of these cyclometalated complexes and the cyclometalated insertion product.

Chapter 4 discusses the reactivity of (Me-PCP)Ir with different oxidants. Reaction with oxygen leads to the dioxygen monomer and dimer complexes, similar in structure to the parent $(\mathrm{PCP}) \mathrm{IrO}_{2}$ complexes. A reaction with DMDO leads to decyclization of the DMDO to form a (Me-PCP)Ir(acetate) complex. Next, the reaction with hydrogen peroxide leads to the mono oxygen complex which further reacts to form a cyclometalated product, similar to those described in Chapter 3. The characterization of this cyclometalated oxygen complex along with a six coordinate cyclometalated CO adduct will be detailed. Finally, the efforts to react nitrous oxide with (Me-PCP)Ir closes this chapter.

Chapter 5 presents a combined experimental and computational study of binding energy determination for the addition of a variety of ligands, which undergo $\mathrm{C}, \mathrm{H}, \mathrm{O}, \mathrm{N}, \mathrm{S}$, and P heteroatom additions, to the metal center of (PCP) $\operatorname{IrHCl},(\mathrm{PCP}) \mathrm{IrH}_{2}$, and the (PCP)Ir fragment. The thermodynamics for the addition of these ligands will be discussed in detail. The experimentally determined values are compared to values derived from DFT calculations utilizing a variety of functionals with good agreement.

Chapter 6 presents the activation of hydrazine and related compounds by the parent (PCP) $\mathrm{IrH}_{2}$ complex. Hydrazine is an important intermediate along the pathway for the synthesis of ammonia from $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$. Both the dehydrogenation of hydrazine by pincer iridium (PCP) type catalysts to $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ as well as the hydrogenation to form ammonia will be discussed. Thermodynamic and kinetics experiments were used to support a computationally calculated mechanism in which hydrazine acts as the hydrogen donor and acceptor rather than promotion by an external reductant or proton source.

## Chapter 2

## Synthesis and General Reactivity of (Me-PCP)Ir Catalyst

#### Abstract

Advantageously, the pincer framework can be easily adapted by changing different aspects of the ligand. The parent (PCP)Ir complex readily activates C-H bonds of aryl rings, possibly leading to oligomerization of (PCP)Ir complexes as a potential decomposition pathway, therefore blocking the para position of the aryl backbone, would hopefully eliminate this possibility and lead to isolation of the catalytically active 14-electron "(PCP)Ir" species. The synthesis and characterization of ( $\mathrm{Me}-\mathrm{PCP}$ ) $\mathrm{IrH}_{\mathrm{n}}$, in which the para position on the backbone of the catalyst has been changed from a hydrogen to a methyl group is reported. The reactivity of this complex in comparison to the parent (PCP)Ir complex is also discussed, for example addition of CO or ethylene leads to four coordinate (Me-PCP)Ir-CO and (Me-PCP)Ir-ethylene complexes, respectively. Finally, attempts to isolate the highly reactive 3-coordinate 14electron (Me-PCP)Ir species are also addressed.

### 2.1 Introduction

The pincer ligand was first introduced by Moulton and Shaw in $1976 .{ }^{1}$ Since that time, the term "pincer" has been applied to many tridentate ligands. ${ }^{2-7}$ One of the advantages of this pincer framework is the ability to adapt the sterics, electronics and reactivity of this complex by making subtle changes. ${ }^{8}$ The R-groups attached to the phosphorous atoms can be changed to methyl (Me), isopropyl (iPr), phenyl (Ph), adamantyl (Ad) ${ }^{9,10}$ or trifluoromethyl $\left(\mathrm{CF}_{3}\right)^{11}$ groups to replace one or more ${ }^{t}$ butyl groups, which can dramatically change the steric environment around the metal center. One or more phosphorous atoms (Z) can be replaced with nitrogen atoms, thereby giving an NCN or a hybrid PCN motif. The methylene linkers (X) can be exchanged with oxygen ${ }^{12}$ or nitrogen ${ }^{13}$ atoms leading to interesting and complicated changes in both the sterics and electronics. The benzene ring can be changed to a pyridyl (PNP) type backbone (Y-position), influencing the electronics of the overall system through trans influence. ${ }^{14}$ Substitutions made along the backbone of the pincer complex $\left(\mathrm{R}_{2}\right)$, specifically replacement of the hydrogen in the para position with $\mathrm{OMe}, \mathrm{CO}_{2} \mathrm{Me}$, or $\mathrm{NMe}_{2}$ groups have been reported, leading to a more controlled, yet less pronounced, effect on the electronics. ${ }^{15}$

Scheme 2.1 General Schematic for a Pincer Ligand

A variety of complexes can be created via chelation of various transition metals including, $\mathrm{Ir}, \mathrm{Rh}$, $\mathrm{Ni}, \mathrm{Pt}, \mathrm{Pd}$, and others. ${ }^{2,16-23}$ Metalation for pincer ligands can occur through a direct process, oxidative addition to carbon halogen bonds, transmetalation, i.e. lithiation, or transcyclometalation. ${ }^{7}$ Direct metalation of pincer ligands for PCP type systems is the preferred method, occurring through C-H or C-C bond activation. The competition between $\mathrm{C}-\mathrm{H}$ activation and $\mathrm{C}-\mathrm{C}$ activation to form the metalated species will be discussed in further detail in the next chapter. For NCN systems, direct cylometalation is less common and pre-coordination often occurs instead, most likely due to a weak $\mathrm{M}-\mathrm{N}$ bond. Therefore, the NCN ligand motifs more readily undergo oxidative addition of an aryl halide to the metal center.

Post metalation, the active catalyst must be generated in order to achieve bond activation or catalytic transformations. The active species or intermediate for the activation of many small molecules including water, ${ }^{24}$ carbon dioxide, ${ }^{25}$ carbon monoxide, dinitrogen, ${ }^{26}$ alkyls and aryls ${ }^{27,28}$ by the parent (PCP) $\operatorname{IrH}_{2}, \mathbf{2 - 1}$, is thought to be the $14 \mathrm{e}^{-}$species, $\mathbf{2 - 3}$. 14 -electron ( $14 \mathrm{e}^{-}$) metal complexes are generally transient species, oftentimes extremely reactive and generated by ligand dissociation in situ. Kaska and Jensen reported a solvated $14 \mathrm{e}^{-}$rhodium species formed by reaction of $(\mathrm{PCP}) \mathrm{Rh}(\mathrm{H})(\mathrm{Cl})$ with a reactive base. ${ }^{29}$ However, this $14 \mathrm{e}^{-}$species was not isolated and only short lived as it further reacts to form more stable species which will be discussed in further chapters of this thesis. Fujita et. al. report the spectroscopic evidence for a transient species generated by photoejection of various small ligands from both the aryl and alkyl (PCP)Rh pincer complexes. ${ }^{30}$ The exact structure, agostic bonding, and solvent interactions of this transient species are unknown which only serves to emphasize the high reactivity of the catalytically active species.

Crabtree et. al reported the use of tert-butylethene (TBE) as an effective acceptor for early studies of dehydrogenation studies, since then the use of TBE has become standard to generate the active $14 \mathrm{e}^{-}$ species. ${ }^{31}$ It has been shown that when $\mathbf{2 - 1}$ is reacted with TBE or the strained cyclic molecule norbornene (NBE), the first equivalent of acceptor is hydrogenated and the second equivalent undergoes either vinylic C-H addition to form $\left.(\mathrm{PCP}) \operatorname{Ir}(\mathrm{H}){ }^{4 \mathrm{Bu}} \mathrm{Vi}\right), \mathbf{2 - 2}$, or in the case of norbornene, it has been proposed that a $\pi$ complex is formed (2-4, Scheme 2.2)..$^{28,32,33}$ Both, the resulting $\pi$-complex and vinylic hydride species are in rapid equilibrium with the proposed $14 \mathrm{e}^{-}$species, 2-3.

Scheme 2.2 Hydrogenation of TBE or NBE and Formation of the Vinyl Hydride and NBE $\pi$ Complexes

In the presence of an aryl solvent such as benzene, toluene or $m$-xylene, C - H activation of the solvent aryl ring prevails over formation of the vinyl hydride or the NBE $\pi$ complex, as a result an aryl hydride complex is synthesized (Scheme 2.3). ${ }^{28}$ Three isomers are formed in the presence of toluene while in $m$-xylene two isomers are formed. There is a preference for $(\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}$ to activate the ortho position of aryls, and, since mesitylene and $p$-xylene are considerably more sterically hindered at the ortho position, these solvents are not activated by (PCP)Ir catalysts. Thus, these two solvents are ideal candidates in which to observe the active catalyst.

Scheme 2.3 C-H Activation of Benzene by (PCP)Ir

2-5

As described for 2-2 and 2-4, species $\mathbf{2 - 5}$ has also been found to undergo rapid exchange via reversible loss of benzene to form the proposed that the $14 \mathrm{e}^{-}$or "naked" (PCP)Ir species, 2-3. This equilibrium will be discussed in further detail in Chapter 5.

As often proposed the stabilization of the $14 \mathrm{e}^{-}$species can be achieved through an agostic or solvated species as described by Kaska and Jensen, and either species may act as the active catalyst. ${ }^{29}$

Different ruthenium pincer complexes have also been reported in which rapid aryl $\mathrm{CH}_{2}$ activation is achieved and even aryl iridium agostic complexes have been characterized. ${ }^{34}$ Kaska and Jensen have previously studied the elimination of TBA from the vinyl hydride species to give a very active intermediate. ${ }^{33}$ Any attempts to characterize and isolate this intermediate proved unsuccessful, yet various possibilities were proposed for the intermediate's structure and stabilization including agostic bonding between TBE and/or solvent, an active $14 \mathrm{e}^{-}$species, or even an agostic interaction between the tert-butyl groups of the pincer backbone (this scenario will be discussed in Chapter 3). The possibility that the catalyst undergoes oligomerization, where the iridium metal center activates the $\mathrm{C}-\mathrm{H}$ bonds of the aryl ring of the subsequent PCP catalyst, has not been previously discussed but may also be a possibility.

Scheme 2.4 Proposed Oligomerization for (PCP)Ir Catalysts

2-6

The ability to eliminate the proposed agostic interaction between subsequent catalyst molecules could possibly lead to isolation or observation of the $14 \mathrm{e}^{-}$species. In this chapter, the synthesis of (Me$\mathrm{PCP}) \mathrm{IrH}_{\mathrm{n}}$, in which the hydrogen in the para position has been replaced with a methyl group will be described. Subsequently, the isolation and characterization of a variety of ( $\mathrm{Me}-\mathrm{PCP}$ ) Ir complexes will be addressed and compared to the parent (PCP)Ir complexes. Finally, the attempts to isolate the active $14 \mathrm{e}^{-}$ (Me-PCP)Ir species will be discussed.

### 2.2 Synthesis of (Me-PCP) IrH $_{n}$

The synthesis of (Me-PCP) $\operatorname{IrH}_{n}, \mathbf{2 - 1 0}$ and 2-11, begins with the synthesis of the (Me-PCP)ligand, 2-8. Phosphination of $3,5-\operatorname{bis}\left(\right.$ bromomethyl ) toluene, 2-7, with di- ${ }^{t}$ butyl phosphine and subsequent heating of this solution followed by workup in a sodium carbonate solution gives 2-8, Scheme 2.5 . ${ }^{35}$ Following the procedure developed by Moulton and Shaw, treatment of 2-8 with iridium cyclooctadiene chloride dimer in toluene and then heating for 3 days yields the metalated hydridochloride species, 2-9 in $82 \%$ yield. ${ }^{1}$ The final step is the reduction of 2-9 to a mixture of $\mathbf{2 - 1 0}$ and $\mathbf{2 - 1 1}$. Species 2-9 is treated with super hydride or
sodium tert-butoxide under a hydrogen atmosphere until the color changes from orange-red to pale yellow, as described in literature. ${ }^{36}$ The ratio of $\mathbf{2 - 1 0}$ to $\mathbf{2 - 1 1}$ is dependent upon the concentration of hydrogen gas. $\mathbf{2 - 1 0}$ can be isolated purely by repeated dissolution and reduced pressure of complex 2-11 in either hexanes or pentane. Conversely, 2-11 can be isolated in pure yield by addition of excess hydrogen to 2-10. Species 2-8 - 11 have been characterized by ${ }^{31} \mathrm{P},{ }^{1} \mathrm{H}$, and ${ }^{13} \mathrm{C}$ NMR spectroscopy; 2-9 was fully characterized including single crystal X-ray analysis.

Scheme 2.5 Synthesis of (Me-PCP) $\operatorname{IrH}_{n}$

### 2.3 Reactivity towards TBE, NBE, CO, Ethylene, Benzene, $\mathbf{N}_{2}$, Benzophenone, and $\mathrm{H}_{2} \mathrm{O}$

Addition of TBE and NBE to $\mathbf{2 - 1 0}$ yields $\mathbf{2 - 1 2}$ and $\mathbf{2 - 1 3}$ which can be observed by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy (Scheme 2.6). ${ }^{28}$ The ${ }^{31} \mathrm{P}$ NMR shift for $\mathbf{2 - 1 2}$ is observed at 71 ppm , whereas the ${ }^{31} \mathrm{P}$ NMR shift of $\mathbf{2 - 1 3}$ is observed at 63 ppm . Species $\mathbf{2 - 1 3}$ is the proposed structure for the addition of NBE to the active species and has only been characterized by ${ }^{31} \mathrm{P}$ NMR spectroscopy. For 2-12, a hydride signal is not observed at room temperature indicating very labile ligands and fast exchange between the active species and the coordinated species.

Scheme 2.6 Formation of the (Me-PCP)Ir Vinyl Hydride and NBE $\pi$ Complexes

The four coordinate carbonyl complex was synthesized by reacting $\mathbf{2 - 1 0}$ with 1 atm of carbon monoxide gas at room temperature (Scheme 2.7). The addition of CO to the parent (PCP)Ir $14 \mathrm{e}^{-}$fragment proceeds to a similar complex. ${ }^{25}$ Species 2-14 was formed in quantitative yield and has been characterized by ${ }^{31} \mathrm{P},{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR and IR spectroscopy. The iridium carbonyl stretching frequency is observed at 1926 $\mathrm{cm}^{-1}$, while $1913 \mathrm{~cm}^{-1}$ has been reported for the parent carbonyl complex.

Scheme 2.7 Synthesis of Four Coordinate (Me-PCP)Ir-CO

Addition of 1 atm of ethylene to the active species generates $\mathbf{2 - 1 5}$ quantitatively (Scheme 2.8). ${ }^{37}$ The ethylene complex is generally hypothesized to be a $\pi$ complex, as the hydrogen signals on the ethylene ligand are equivalent and observed as a singlet at 3.4 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum. A singlet is observed at approximately 59.6 ppm in the ${ }^{31} \mathrm{P}$ NMR spectrum. These shifts are comparable to those observed for the parent complex.

Scheme 2.8 Reaction of (Me-PCP) $\mathrm{IrH}_{2}$ and Ethylene

As was observed with the parent complex, when $\mathbf{2 - 1 0}$ is reacted with a hydrogen acceptor in benzene, then the C-H activation product $(\mathrm{Me}-\mathrm{PCP}) \operatorname{Ir}(\mathrm{Ph})(\mathrm{H}), \mathbf{2 - 1 6}$, is synthesized quantitatively (Scheme 2.9). ${ }^{28}$ This complex has comparative spectroscopic data to the parent complex, 2-5, and the hydride signal is not observed at room temperature.

Scheme 2.9 Reaction of (Me-PCP) $\mathrm{IrH}_{2}$ and Benzene

One of the most well used methods for drying a variety of alkane type solvents is the combination of sodium metal and benzephenone to produce a dibenzoketyl which then reacts with residual water and oxygen. This method was initially used to dry mesitylene in this study. In certain reactions, an unidentified signal was observed in the ${ }^{31} \mathrm{P}$ NMR spectrum at 59 ppm . It was discovered that excess benzophenone in mesitylene reacted with the active catalyst to form the $\mathrm{C}-\mathrm{H}$ activation product of benzophenone, 2-17 (Scheme 2.10). The most likely position for C-H activation is para to the ketone. This species has not been previously isolated for the parent complex, but presumably similar reactivity would be observed. This method of drying was no longer utilized for the remainder of this work.

Scheme 2.10 Reaction of (Me-PCP) $\mathrm{IrH}_{2}$ and Benzophenone

Reaction of the active species, arising from $\mathbf{2 - 1 0}$, under a nitrogen atmosphere leads to a combination of the dinitrogen monomer, 2-18, and dinitrogen dimer, $\mathbf{2 - 1 9}$, in which $\mathrm{N}_{2}$ bridges two metal centers (Scheme 2.11). ${ }^{26,33}$ Oftentimes, the nitrogen species are described as inert and unreactive. The parent (PCP) $\mathrm{IrN}_{2}$ monomer and dimer complexes will be discussed in more detail in Chapter 6.

Scheme 2.11 Reaction of (Me-PCP) $\mathrm{IrH}_{2}$ and Nitrogen

Oxidative addition of water to the active species leads to formation of the hydrido hydroxyl species, 2-20 (Scheme 2.12). ${ }^{24}$ A doublet is observed in the ${ }^{31} \mathrm{P}$ NMR spectrum at 64.87 ppm due to the coupling between the phosphorous and the hydride proton. The hydride proton is observed at -31.0 ppm and the hydroxyl proton is observed as a broad singlet at 5.28 in the ${ }^{1} \mathrm{H}$ NMR spectrum. These shifts are comparable to those observed for the parent complex.

Scheme 2.12 Addition of $\mathrm{H}_{2} \mathrm{O}$ to (PCP)Ir

### 2.4 Attempts to Synthesize (Me-PCP)Ir 14-Electron Species

In an attempt to observe either the $14 \mathrm{e}^{-}$species or a species stabilized by agostic interactions, the 2-12 was evacuated in an attempt to remove TBE and shift the equilibrium towards the $14 \mathrm{e}^{-}$species. In a $\mathbf{J}$. Young NMR tube, a solution of either 2-12 or 2-13 was placed under vacuum to remove excess volatiles and approximately half the solvent which was followed by addition of fresh solvent. The solution was monitored by NMR spectroscopy and this procedure was repeated multiple times. Instead of observing any $14 \mathrm{e}^{-}$species, the catalyst scavenges the atmosphere of the NMR tube, and other less labile ligands oxidatively add to the $14 \mathrm{e}^{-}$species, leading to observation of $\mathbf{2 - 1 4}, \mathbf{2 - 1 8}, \mathbf{2 - 1 9}$, and $\mathbf{2 - 2 0}$ complexes.

Reactions were completed in $p$-xylene and mesitylene, with different solvent volumes, varying ratios of acceptor to catalyst, and in all cases multiple species were observed by ${ }^{31} \mathrm{P}$ NMR spectroscopy with the major species as complexes $\mathbf{2 - 1 4}, \mathbf{2 - 1 8}, \mathbf{2 - 1 9}$, and $\mathbf{2 - 2 0}$. The results from these experiments were inconclusive.

### 2.5 Summary

A new pincer complex, (Me-PCP) $\operatorname{IrH}_{n}$ was synthesized which exhibits similar reactivity as that of the parent $(\mathrm{PCP}) \mathrm{IrH}_{\mathrm{n}}$ species. The pincer iridium complexes with water, carbon monoxide, ethylene, benzene, benzophenone, and nitrogen have been isolated successfully. However, the active $14 \mathrm{e}^{-}$species has elusively evaded all attempts to be isolated and/or observed. The reasoning for its nonobservance will be discussed further in subsequent chapters.

### 2.6 Experimental

## General

All reactions were performed under an argon atmosphere using standard Schlenck techniques or in an argon-filled glove box. $\mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{C}_{6} \mathrm{D}_{6}$, TBE, and $p$-xylene- $d_{10}$ were dried over $\mathrm{Na} / \mathrm{K}$ alloy and collected via vacuum transfer. NBE was sublimed before use. All other substrates were degassed before entry to glovebox and used without further purification. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$, and ${ }^{31} \mathrm{P}$ NMR spectra were obtained from either a 400 or 500 MHz Varian instrument. The residual peak of the deuterated solvent was used as a reference for all ${ }^{1} \mathrm{H}$ NMR spectra and an internal capillary standard of $\mathrm{PMe}_{3}$ in $p$-xylene- $d_{10}(-62.4 \mathrm{ppm})$ was used to reference ${ }^{31} \mathrm{P}$ NMR chemical shifts.

## (Me-PCP) ligand, 2-8 ${ }^{35}$

4.75 g ( 17.2 mmol ) 3,5-bis(bromomethyltoluene) was refluxed with $5.0 \mathrm{~g}(34 \mathrm{mmol})$ di-tbutyl phosphine in 40 mL degassed acetone for 45 minutes. A white precipitate was formed after cooling to room temperature. A degassed solution of $15.3 \mathrm{~g} \mathrm{Na}_{2} \mathrm{CO}_{3}$ in $65 \mathrm{~mL} \mathrm{H}_{2} \mathrm{O}$ was added. The resulting mixture was heated at $80^{\circ} \mathrm{C}$ overnight with stirring. Upon cooling, the water layer was decanted into a clean 100 mL flask and the solvent was removed via vacuum from the resulting oil, leaving behind a tan solid. 40 mL ether was added to solid and ether layer was decanted to clean flask and the sample was pulled to dryness. The final product was a tan solid isolated in $90 \%$ yield. ${ }^{\mathbf{3 1}} \mathbf{P} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 33.62$
(s). ${ }^{1} \mathbf{H}$ NMR ( $\left.\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{4 0 0} \mathbf{~ M H z}\right): \delta 7.12(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 2.76\left(\mathrm{~d}\right.$ of $\left.\mathrm{vt}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.16\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.08$ $\left(\mathrm{d}, J_{P H}=10.8 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right) .{ }^{13} \mathbf{C} \mathbf{N M R}\left(\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{1 0 0 . 6}, \mathbf{M H z}\right): \delta 127.9\left(\mathrm{t}, \mathrm{CH}_{2}\right), 31.7\left(\mathrm{~s}, C \mathrm{H}_{3}\right), 29.8(\mathrm{~d}$, $\left.P^{\prime} B u\right)$.

## (Me-PCP)IrHCl, 2-9 ${ }^{l}$

$[\mathrm{IrCl}(\text { cyclooctadiene })]_{2}(1.01 \mathrm{~g}, 1.5 \mathrm{mmol})$ was added to 1.18 g ( 3 mmol$)$ of (Me-PCP) ligand in toluene at room temperature. Mixture was heated under reflux for $72+\mathrm{hrs}$ with stirring under $\mathrm{H}_{2}$ atmosphere and the solvent was removed under vacuum. The resulting solid was extracted with hexane, recrystallized by slow evaporation from benzene and gave a yield of $0.790 \mathrm{~g}(82.2 \%)$ of the complex as dark red crystals. The crystal structure is shown as Figure 2.1 while X-ray crystallography refinement and structure parameters are included in Tables 2.1 through 2.6 . ${ }^{31} \mathbf{P} \mathbf{N M R}\left(\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 68.26\left(\mathrm{~d}, \boldsymbol{J}_{P H}\right.$ $=16.5 \mathrm{~Hz},(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrHCl}), 67.52\left(\mathrm{~d}, J_{P H}=29.5,(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrHBr}\right) .{ }^{1} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{6} \mathbf{D}_{6}, \mathbf{4 0 0} \mathbf{M H z}\right): \delta 7.121$ ( $\mathrm{s}, 2 \mathrm{H},(\mathrm{Me}-\mathrm{PCP})$ IrHCl Ar- $H$ ), 6.799 ( $\mathrm{s}, 2 \mathrm{H},(\mathrm{Me}-\mathrm{PCP})$ IrHBr Ar- $H$ ), 3.067 ( d of vt, $J_{\mathrm{PH}}=3.75, J_{\mathrm{HH}}=17.5$, $2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}$ ), $2.975\left(\mathrm{~d}\right.$ of vt, $J_{P H}=3.75, J_{\mathrm{HH}}=17.5,2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}$ ), $2.269\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 2.250(\mathrm{~s}, 3 \mathrm{H}$, (MePCP) IrHBr Ar-CH $)_{3}$ ), $1.269\left(\mathrm{t}, J_{\mathrm{PH}}=6.5 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.217\left(\mathrm{t}, J_{\mathrm{PH}}=6.75 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right),-42.818\left(\mathrm{t}, J_{\mathrm{PH}}\right.$ $=12.75,1 \mathrm{H}, \mathrm{Ir}-H)$.

## (Me-PCP) $\mathbf{I r H}_{\mathrm{n}}, \mathbf{2 - 1 0}$ and 2-11

Method 1: ${ }^{38} \mathrm{~A}$ solution of $100.1 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrHCl}(0.157 \mathrm{mmol})$ in pentane was saturated with $\mathrm{H}_{2}$ at room temperature. To this solution, 0.24 mL of a $1 \mathrm{M} \mathrm{LiBEt}{ }_{3} \mathrm{H}$ in $\mathrm{THF}(0.24 \mathrm{mmol})$ was added dropwise until the solution changed from an orange red to a pale yellow and some white precipitate was formed. The solution was filtered and solvent was removed in vacuo leaving behind a red-brown mixture as the dihydride and tetrahydride. Method 2: $100.6 \mathrm{mg} \mathrm{NaO}^{\prime} \mathrm{Bu}(1.05 \mathrm{mmol})$ and 249.5 mg (Me-PCP)IrHCl $(0.392 \mathrm{mmol})$ are both added to Schlenck flask. Solids are dissolved in 60 mL benzene. Solution is stirred while $\mathrm{H}_{2}$ was bubbled through solution for 3.5 hours. Solution turned from a dark red color to light orange. Solution was filtered and solvent was removed under vacuum and orange-red crystals are left as final product in $0.236 \mathrm{~g}(90 \%)$ yield. ${ }^{31} \mathbf{P}$ NMR ( $\left.\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 86.97(\mathrm{~s}, \mathrm{Me}-\mathrm{PCP}) \mathrm{IrH}_{2}$ ), $73.96(\mathrm{~s}, \mathrm{Me}-$ PCP) $\mathrm{IrH}_{4}$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\left.\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{4 0 0} \mathbf{~ M H z}\right): \delta(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrH}_{2}: 7.17(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.54\left(\mathrm{t}, J_{P H}=3.0 \mathrm{~Hz}, 4 \mathrm{H}\right.$, $\mathrm{CH}_{2} \mathrm{P}$ ), $2.35\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{PCP}-\mathrm{CH}_{3}\right), 1.26\left(\mathrm{t}, J_{P H}=6.4 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{\prime} \mathrm{Bu}\right),-19.38\left(\mathrm{t}, J_{P H}=8.6 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ir} \mathrm{H}_{2}\right)$. (Me-

PCP) $\mathrm{IrH}_{4}: 6.91(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.29\left(\mathrm{t}, J_{P H}=2.8 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.35\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}^{2} \mathrm{CH}_{3}\right), 1.20\left(\mathrm{t}, J_{P H}=6.6 \mathrm{~Hz}\right.$, $\left.36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right),-9.10\left(\mathrm{t}, J_{P H}=9.6 \mathrm{~Hz}, 4 \mathrm{H}, \operatorname{Ir} H_{4}\right) .{ }^{\mathbf{1 3}} \mathbf{C} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 0 0 . 6} \mathbf{~ M H z}\right): \delta 158.24(\mathrm{t}$, aromatic C-Ir), $136.632\left(\mathrm{~s}\right.$, aromatic), $128.02\left(\mathrm{t}, \mathrm{C}_{6} \mathrm{D}_{6}\right.$ and aromatic), $121.00(\mathrm{t}, \mathrm{Ar}), 40.35\left(\mathrm{t}, \mathrm{CH}_{2} \mathrm{P}\right), 34.40\left(\mathrm{q}, C\left(\mathrm{CH}_{3}\right)_{3}\right)$, $30.01\left(\mathrm{t}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right), 22.14\left(\mathrm{~s}, \mathrm{Ar}-\mathrm{CH}_{3}\right)$.

## (Me-PCP)Ir(TBE), 2-12

5 mg of the mixture of $\mathbf{2 - 9}$ and $\mathbf{2 - 1 0}$ was dissolved in $p$-xylene- $d_{10}$ and 0.05 mL TBE ( 0.387 mmol) was added to the solution. After ten minutes, the solution changed from red to dark red in color. The compound was characterized in situ. ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{10}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}$ ): $\delta 70.88$ (s). ${ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}$ ( $\boldsymbol{p}$ -xylene- $\left.d_{10}, 500 \mathrm{MHz}\right): \delta 7.31(\mathrm{~s}, 2 \mathrm{H}, \operatorname{Ar}-H), 6.18(\mathrm{~m}, \mathrm{TBE}), 5.30(\mathrm{~d}, \mathrm{TBE}), 5.21(\mathrm{bs}, \mathrm{TBE}), 3.73\left(\mathrm{vt}, J_{P H}=\right.$ $\left.3.6 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.54\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.55\left(\mathrm{vt}, J_{P H}=6.4 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.39(\mathrm{t}, \mathrm{TBE})$.

## (Me-PCP)IrNBE, 2-13

5 mg of the mixture of 2-9 and 2-10 was dissolved in $p$-xylene- $d_{10}$ and excess NBE was added to the solution. After five minutes, the solution changed from red to orange in color. The compound was characterized in situ. ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 63.4$ (s).

## (Me-PCP)Ir-CO, 2-14

To a solution of $9.5 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(15.8 \mu \mathrm{~mol})$ in pentane, 1 atm CO was added in a J . Young NMR tube. Solution changed from dark red to yellow in color. The solvent was removed solvent in vacuo, leaving a yellow solid which was dissolved in $\mathrm{C}_{6} \mathrm{D}_{6}$. (Me-PCP)IrCO was formed in $98 \%$ yield as determined by NMR spectroscopy. ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR $\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}\right): \delta 83.15(\mathrm{~s}) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{5 0 0}\right.$ $\mathbf{M H z}): \delta 7.04(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.41\left(\mathrm{vt}, J_{P H}=3.0 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.35\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.29\left(\mathrm{vt}, J_{P H}=6.5\right.$ $\left.\mathrm{Hz}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right) .{ }^{\mathbf{1 3}} \mathbf{C}$ NMR ( $\left.\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 2 5 . 6 7} \mathbf{~ M H z}\right): \delta 208.77(\mathrm{~s}, \mathrm{Ir}-\mathrm{CO}), 156.02(\mathrm{~s}, \sigma-C), 128.4(\mathrm{~s}, \rho-C)$, $121.44\left(\mathrm{vt}, J_{P C}=6.8 \mathrm{~Hz}, C\left(\mathrm{CH}_{3}\right)_{3}\right), 34.50\left(\mathrm{~s}, C \mathrm{H}_{3}\right), 29.84\left(\mathrm{vt}, J_{P C}=2.2 \mathrm{~Hz}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right), 22.78(\mathrm{~s}), 14.33(\mathrm{~s})$. IR (KBr, $\mathbf{c m}^{-1}$ ): $v_{\text {IrCO }}=1926.4(\mathrm{~s})$.

## (Me-PCP)Ir(ethylene), 2-15

To a solution of $9.5 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(15.8 \mu \mathrm{~mol})$ in pentane, 1 atm ethylene was added in a J . Young NMR tube. Solution changed from dark red to brown in color. Remove solvent in vacuo, leaving a
brown solid which was dissolved in $p$-xylene- $d_{10}$. (Me-PCP)Ir-ethylene was formed in $98 \%$ yield as determined by NMR spectroscopy. ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene ${ }_{\boldsymbol{d} \mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 59.62(\mathrm{~s}) .{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$ xylene $\left._{d 10}, 400 \mathrm{MHz}\right): \delta 7.070(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-H), 7.009(\mathrm{~s}, 1 \mathrm{H}, \operatorname{Ar}-H), 3.42$ ( $\mathrm{vt}, J=3.4 \mathrm{~Hz}, 4 \mathrm{H}$, ethylene), 3.27 (vt, $J=3.0 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}$ ), $3.98\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.26\left(\mathrm{t}, J=5.8 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{bu}\right)$.

## (Me-PCP) $\operatorname{Ir}(\mathbf{P h})(\mathbf{H}), \mathbf{2 - 1 6}$

To a solution of $9.5 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(15.8 \mu \mathrm{~mol})$ in $p$-xylene- $d_{10}$, a solution of $90 \mu \mathrm{~L} \mathrm{C}_{6} \mathrm{H}_{6}(1.01$ mmol ) in $140 \mu \mathrm{~L}$ TBE ( 1.09 mmol ) was added in a J. Young NMR tube. Solution was mixed and NMR characterization completed. ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}$ ): $\delta 68.06$ (s). ${ }^{1} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{10}$, $500 \mathrm{MHz}): \delta 6.82(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar}-H), 2.03\left(\mathrm{vt}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 1.53\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}^{2}-\mathrm{CH}_{3}\right), 0.872\left(\mathrm{~s}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right)$.

## (Me-PCP) $\operatorname{Ir}(\mathbf{H})$ (Benzophenone), 2-17

To a solution of $9.5 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(15.8 \mu \mathrm{~mol})$ in $\mathrm{C}_{6} \mathrm{D}_{6}$, a solution of excess benzophenone in $140 \mu \mathrm{~L}$ TBE ( 1.09 mmol ) was added in a J. Young NMR tube. Solution was mixed and NMR characterization completed. ${ }^{\mathbf{3 1}} \mathbf{P} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}\right): \delta 58.65(\mathrm{~s}) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{5 0 0} \mathbf{~ M H z}\right): \delta$ $7.97(\mathrm{~d}, 2 \mathrm{H}$, aromatic), $7.92(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}-H), 7.80(\mathrm{t}, 4 \mathrm{H}, \mathrm{Ar}-H), 7.76(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}-H), 7.32(\mathrm{t}, 8 \mathrm{H}, \mathrm{Ar}-H), 7.28$ (s, 1H, Ar-H), 3.31 (d of vt, $2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}$ ), 3.03 (d of vt, $2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}$ ), $2.40\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.42(\mathrm{t}, 18 \mathrm{H}$, $\left.\mathrm{P}^{t} \mathrm{Bu}_{2}\right), 1.13\left(\mathrm{t}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right),-9.023(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ir}-H)$.

## (Me-PCP) IrN $_{2}$ monomer, 2-18, and (Me-PCP) IrN $_{2}$ dimer, 2-19

In a J. Young NMR tube, a solution of $9.5 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(16 \mu \mathrm{~mol})$ in $p$-xylene- $d_{10}$ was degassed and $1 \mathrm{~atm} \mathrm{~N}_{2}$ was added. Upon mixing the solution changed from dark red to orange. Both the monomer and dimer were observed in solution by NMR spectroscopy. (Me-PCP)IrN $\mathbf{I}_{\mathbf{2}}$ monomer, 2-18: ${ }^{31}$ P NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}$ ): $\delta 73.24(\mathrm{~s}) .{ }^{\mathbf{1}} \mathrm{H}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{5 0 0} \mathbf{~ M H z}$ ): $\delta 6.86(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-$ $H), 6.53(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-H), 3.18\left(\mathrm{vt}, J=3.80 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.31\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.35(\mathrm{t}, 36 \mathrm{H}, J=6.3 \mathrm{~Hz}$, $\mathrm{P}^{t}$ bu). (Me-PCP)IrN $\mathbf{N}_{\mathbf{2}}$ dimer, 2-19: ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}$ ): $\delta 74.9$ ( s ). ${ }^{\mathbf{1}} \mathrm{H}$ NMR ( $\boldsymbol{p}$-xylene$\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{5 0 0} \mathrm{MHz}\right): \delta 6.90(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-H), 6.60(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-H), 3.20\left(\mathrm{vt}, 4 \mathrm{H}, J=2.9 \mathrm{~Hz}, \mathrm{CH}_{2} \mathrm{P}\right), 2.35(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-$ $\left.\mathrm{CH}_{3}\right), 1.42\left(\mathrm{t}, J=6.4 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{\mathrm{t}} \mathrm{bu}\right)$.

## (Me-PCP)Ir(H)(OH), 2-20

5 mg of a mixture of $\mathbf{2 - 9}$ and $\mathbf{2 - 1 0}$ was dissolved in $p$-xylene $-d_{10}$ and 0.05 mL TBE ( 0.4 mmol ) was added to the solution. After ten minutes, the solution changed from red to dark red in color. $0.2 \mu \mathrm{~L}$ (11 umol) degassed, deionized water was added and solution was mixed. The compound was characterized in situ. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 64.87$ (d). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{~ M H z}$ ): $\delta 7.30$ (s, $2 \mathrm{H}, \mathrm{Ar}-H), 5.28(\mathrm{bs}, 1 \mathrm{H}, \mathrm{Ir}-\mathrm{OH}), 3.30\left(\mathrm{~d}\right.$ of vt, $\left.J_{P H}=16 \mathrm{~Hz}, J_{H H}=4 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 3.19\left(\mathrm{~d}\right.$ of vt, $J_{P H}=16$ $\left.\mathrm{Hz}, J_{H H}=4 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.54\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}^{2} \mathrm{CH}_{3}\right), 1.57\left(\mathrm{t}, J_{P H}=6 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P} \mathrm{t} \mathrm{bu}\right), 1.48\left(\mathrm{t}, J_{P H}=6 \mathrm{~Hz}, 18 \mathrm{H}\right.$, $\left.\mathrm{P}^{t} \mathrm{bu}\right),-31.0\left(\mathrm{t}, J_{P H}=12 \mathrm{~Hz}, \mathrm{Ir}-H\right)$.

## Reaction of 2-12 under vacuum

5 mg of a mixture of $\mathbf{2 - 9}$ and $\mathbf{2 - 1 0}$ was dissolved in $p-x y l e n e-d_{10}$ and 0.05 mL TBE $(0.4 \mathrm{mmol})$ was added to the solution. After ten minutes, the solution changed from red to dark red in color. Excess volatiles and $\sim 50 \%$ solvent were removed followed by addition of fresh solvent. Process was repeated multiple times and NMR spectra were obtained. Multiple complexes were observed by ${ }^{31} \mathrm{P}$ NMR spectroscopy including 2-14, 2-18, 2-19, and 2-20.

## Chapter 3

## Synthesis of Cyclometalated (PCP)Ir Complexes

#### Abstract

Pincer complexes have been well documented as excellent C-H activation catalysts. The structure of the active catalytic species has evaded elucidation but has been proposed as a $14 \mathrm{e}^{-}$, agostic, solvated, or dimeric species via C-H activation of a subsequent PCP ligand backbone. Rather than isolation or observation of any of these proposed species, it has been found that the cyclometalation or $\mathrm{C}-\mathrm{H}$ activation of the tbutyl group attached to one of the phosphorous atoms occurs readily. Characterization of cyclometalated complexes is described along with an interesting cyclometalated insertion product which occurs upon reaction of a cyclometalated product with carbon monoxide. Two different mechanisms are proposed and discussed in relation previously cited pathways for the formation of cyclometalated complexes and synthesis of the cyclometalated insertion product.

### 3.1 Introduction

Initial synthesis of the pincer complex requires cyclometalation of the pincer ligand. As mentioned in chapter 2, the preferred method for synthesis of PCP systems is direct metalation of the pincer ligand via intermolecular C-H or C-C bond activation (Scheme 3.1). Whereas C-H activation of A-H and C-C activation of $\mathbf{A}-\mathbf{C H}_{3}$ leads to the formation of the tridentate (PCP)M system, B, C-H bond activation of $\mathbf{A -} \mathbf{C H}_{\mathbf{3}}$ leads to the formation of $\mathbf{C}$, in which a carbon bond has been inserted into the metal-backbone linkage.

Scheme 3.1 C-C and C-H Activation of Pincer Ligands

Milstein and coworkers have studied the formation of these C-H activation products extensively and have reported many pincer complexes with various metal centers (Figure 3.1). ${ }^{1-7}$ These products exhibit a unique splitting pattern for the inequivalent splitting of the methylene protons $\left(\mathrm{ArCH}_{2} \mathrm{P}\right)$, as well as a signal for $\mathrm{ArCH}_{2} \mathrm{M}$ protons in the ${ }^{1} \mathrm{H}$ NMR spectra, whereas the splitting pattern of two inequivalent phosphorous atoms in the ${ }^{31} \mathrm{P}$ NMR spectra is distinct and the P-P coupling is observable and quite large.

Figure 3.1 Milstein Examples of C-H Activation Products

$$
\mathrm{R}=\mathrm{Ph},{ }^{i} \mathrm{Pr}
$$

$\mathbf{R}={ }^{\mathrm{t}} \mathrm{Bu}, \mathrm{Ph},{ }^{\mathbf{i}} \mathbf{P r}$
$R^{\prime}=\mathrm{H}, \mathrm{OMe}$
$\mathbf{M}=\mathbf{R h}, \mathbf{I r}, \mathbf{R u}$
$L=\mathrm{PPh}_{3}, \mathrm{H}$, Aryl $L_{2}=\mathrm{Cl}, \mathrm{I}$

Various intermediates have been proposed to explain the appearance of both the inserted C - H activation products as well as the $\mathbf{C - C}$ activation products (Scheme 3.2). In all cases, intermediate $\mathbf{D}$, in
which both phosphorous atoms are chelated to the metal center, is critical in the formation of both the $\mathrm{C}-\mathrm{H}$ activation and C-C bond activation products. When the metal center is iridium or rhodium ( $\mathrm{M}=\mathrm{Ir}$ or Rh ), the C-H and C-C pathways are parallel processes; direct insertion of the metal into the $\mathrm{Ar}-\mathrm{CH}_{3}$ bond yields $\mathrm{a}(\mathrm{PCP}) \mathrm{M}$ motif and direct $\mathrm{C}-\mathrm{H}$ activation of $\mathrm{Ar}-\mathrm{CH}_{3}$ yields the inserted product. ${ }^{3}$ The $\mathrm{C}-\mathrm{C}$ bond activation process is slightly more favorable than the $\mathrm{C}-\mathrm{H}$ activation process, with respect to kinetics and thermodynamics, hence the (PCP)M motif is the more easily isolated species. If the metal center is ruthenium or platinum $(\mathrm{M}=\mathrm{Ru}$ or Pt$)$, then $\mathrm{C}-\mathrm{H}$ activation yields the expected activation product which subsequently leads to the C-C bond activation product through either intermediate $\mathbf{E}$ or $\mathbf{F} .{ }^{5}$ Intermediate $\mathbf{E}$ is a three centered transition state in which little to no interaction from the aryl $\pi$ system is required. Intermediate $\mathbf{F}$ is a $\sigma$-arenium species in which the electron density has been removed from the aryl ring and transferred to the metal center. In this scenario, C-C bond activation is only thermodynamically favored whereas C-H activation is kinetically preferred. More work must be completed to harness these selectivity differences between different metal centers and pincer ligands.

Scheme 3.2 Formation of Proposed Intermediates in the C-H and C-C Bond Activation Pathways

Goldman and coworkers report a similar series of inserted products with acetate type ligands (Figure 3.2). ${ }^{8}$ These products exhibit the same splitting pattern for inequivalent methylene protons, a signal for $\mathrm{ArCH}_{2} \mathrm{M}$ protons in the ${ }^{1} \mathrm{H}$ NMR spectra, and the splitting pattern for two inequivalent phosphorous atoms in the ${ }^{31} \mathrm{P}$ NMR spectrum with a large P-P coupling as was observed for the $\mathrm{C}-\mathrm{H}$ activation products published by Milstein. However, the synthesis of these inserted acetate products occurs via methylidene insertion into the aryl $\mathrm{Ir}-\mathrm{C}(\mathrm{ipso})$ bond rather than direct $\mathrm{C}-\mathrm{H}$ activation of a phosphinated xylene ligand, A-
$\mathbf{C H}_{3}$ (Scheme 3.1). Intermediate $\mathbf{D}$ is cited as quite accessible via computational methods for the $\mathbf{C}-\mathrm{H}$ reductive elimination of these (PCP) $\operatorname{Ir}$ (acetate) complexes and most likely the intermediate for the methylidene migration.

Figure 3.2 Inserted (PCP) Ir(acetate) Products

Interestingly, the C-H bond activation discussed above occurs in an intermolecular fashion. As proposed in the previous chapter, the intramolecular C-H activation at an aryl backbone of a second molecule of a pincer complex to form a dimer or oligomer, however, this type of scenario has not been supported by experimental evidence. Although the rigidity of the backbone inhibits C-H activation, it does not eliminate the possibility that the pincer complex can undergo a different intramolecular C-H activation at the phosphorous linked substituent $(\mathrm{R})$ instead of aryl C-H bonds. This intramolecular C-H activation leads to a cyclometalated complex in which the C-H bond of one ${ }^{t}$ butyl arm oxidatively adds to the iridium center to create an additional four membered ring (Figure 3.3).

In 1983, Kaska reported the reaction of $(\mathrm{PCP}) \mathrm{RhHCl}$ with $\mathrm{NaN}\left(\mathrm{SiMe}_{3}\right)_{2}$ to yield the (PCP)Rh solvated complex, the C-H addition product of the solvent, and observation of $\mathrm{C}-\mathrm{H}$ activation at the ${ }^{t}$ butyl substituent of one of the (PCP)Rh arms. ${ }^{9}$ This was the first report in which intramolecular C-H activation of the tbutyl groups competes with intermolecular C-H activation of other ligands in the system. The first isolated iridium example was a crystallized sample of cyclometalated (MeO-PCP)IrCl showing the cyclometalation of the ${ }^{t}$ butyl arm. ${ }^{10}$ An equilibrium exists between (MeO-PCP) IrHCl and the cyclometalated complex upon loss of $\mathrm{H}_{2}$ from the system. The additional four membered ring leads to loss of symmetry within the molecule, therefore the ${ }^{31} \mathrm{P}$ NMR spectra of these species are reported as two doublets with relatively large P-P coupling. The (MeO-PCP)IrHCl cyclometalated complex has reported ${ }^{31} \mathrm{P}$ NMR shifts of 50.8 and 9.8 with $J_{P P}=351.1 \mathrm{~Hz}$ for the trans positioning of the inequivalent phosphorous atoms. There is no indication of a hydride or a weakly bound hydrogen ligand. Other
examples, replacing the para methoxy substituent of the (PCP)Ir aryl backbone with a hydroxyl or nitro group, have also been cited. Cundari and Gunnoe reported a ruthenium example in which (PCP) $\mathrm{Ru}\left(\mathrm{NH}_{2}\right)(\mathrm{CO})$ can eliminate $\mathrm{NH}_{3}$ to form a cyclometalated CO complex. ${ }^{11}$ The ${ }^{31} \mathrm{P}$ NMR spectrum for this species shows a doublet of doublets at 82.7 and 46.3 ppm with $J_{\mathrm{PP}}=245 \mathrm{~Hz}$. A few (POCOP)Ir examples were published in which both five and six coordinate cyclometalated species are formed in which the ligand is $\mathrm{CO}, \mathrm{Cl}$, or acetonitrile. ${ }^{12}$ The ${ }^{31} \mathrm{P}$ NMR spectra for these species are shifted much farther downfield (154 and 87 ppm ) and $J_{\mathrm{PP}}=333 \mathrm{~Hz}$, consistent with the general downfield shift of POCOP complexes versus PCP complexes. ${ }^{13}$ Periana and Goddard report a ( PNP ) $\mathrm{IrI}_{2}$ cyclometalated complex synthesized from reaction of the PNP ligand and $\operatorname{IrCl}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}^{14}$ and the Goldman group has prepared and characterized a (PCP) $\operatorname{Ir}$ (acetate) cyclometalated complex. ${ }^{8}$

Figure 3.3 Examples of Cyclometalated Pincer Complexes

The electronics of the ligand backbone may have a significant effect on the isolation of these cyclometalated complexes. A series of resonance structures have been proposed for the (PCP)Ir complexes, in which the iridium metal center can be negative, neutral or positive in charge (Scheme 3.3). Modifications of the para-substituent can help achieve or influence the major resonance structure of the complex. A $\sigma$-donating methoxy or hydroxyl substituent leads to stabilization of electron density on the iridium center, facilitating intramolecular oxidative addition of the ${ }^{t}$ butyl $\mathrm{C}-\mathrm{H}$ bond within a short time frame. Conversely, the electron withdrawing nitro group facilitates conversion to the cylometalation complex in a few months and the cyclometalated parent (PCP)Ir complex, in which the para substituent is a hydrogen, was not isolated. Based on these resonance structures, $\pi$-donating or withdrawing characteristics of different substituents dominate the resonance structures and lead to synthesis of the cyclometalated complexes. Within the POCOP example isolated by Koridze the para position is occupied by a hydrogen instead of a significantly electron withdrawing or donating substituents. POCOP ligands generally allow
for a significant buildup of negative charge on the ipso carbon versus the parent PCP ligand which could lead to increased chance of cyclometalation. ${ }^{15}$

Scheme 3.3 Resonance Structures for (PCP)Ir Complexes

Alternatively, different computational and experimental studies have been conducted to elucidate some of the substituent effects on the addition of ligands to (PCP)Ir species. ${ }^{16}$ It has been found that increased electron donation from the para substituent leads to increased $\mathrm{C}_{i p s o}$ - Ir bond lengths due to repulsion between the filled $d$ orbitals of the iridium metal center and the PCP $p(\pi)$ orbitals in the $14 e^{-}$ species. Addition of $\mathrm{H}_{2}$ mitigates this scenario and electron donating substituents on the PCP backbone leads to strengthening and shortening of C-Ir bonds. These results do not fully agree with the resonance structures proposed as shorter double bonds between the ipso carbon and iridium are depicted.

Kaska has proposed a mechanism for the formation of these cyclometalated species proceeding through two different pathways (Figure 3.4). The initial step is the formation of a $14 \mathrm{e}^{-}$species in which coordination of the two $\mathrm{PH}_{3}$ groups occurs prior to C-H activation of the aryl ring. As discussed earlier in Chapter 2, $14 \mathrm{e}^{-}$species are not stable but have been reported for other metal complexes. ${ }^{9,17}$ The precoordination of phosphines to the metal center prior to activation of the aryl ring has also been cited as an important intermediate by Milstein during his studies of the inserted products discussed in the beginning of this chapter. ${ }^{3,5}$ After formation of the $14 \mathrm{e}^{-}$species, there are two possible pathways. In pathway A , the ${ }^{t}$ butyl C-H bond oxidatively adds to the iridium followed by $\mathrm{C}-\mathrm{H}$ activation of the aryl bond in the PCP backbone. In pathway $\mathrm{B}, \mathrm{C}-\mathrm{H}$ activation of the aryl ring is favored over $\mathrm{C}-\mathrm{H}$ activation of ${ }^{t}$ butyl, to give the (PCP) IrHCl complex. Then attack of the tbutyl at a free coordination site opposite the hydride leads to a seven coordinate $\operatorname{Ir}(\mathrm{V})$ complex upon rearrangement. The equilibrium is favored for the formation of (PCP)IrHCl due to the strength of the aryl carbon-iridium bond, but loss of $\mathrm{H}_{2}$ makes the reaction irreversible to give cyclometalated (PCP) IrCl.

Figure 3.4 Proposed Mechanism for the Formation of Cyclometalated Complexes

Pathway A

In this chapter, the synthesis and characterization $\left({ }^{31} \mathrm{P},{ }^{19} \mathrm{~F},{ }^{13} \mathrm{C},{ }^{1} \mathrm{H}\right.$ and 2D gCOSY NMR spectroscopy) of different cyclometalated species will be detailed. In one case the introduction of CO gas into the system leads to the insertion of the C-H activated ${ }^{t}$ butyl group into the aryl-iridium bond of the backbone. The mechanistic pathways for the formation of the cyclometalated complexes and the inserted product will be discussed in relation to those proposed by Milstein and Kaska.

### 3.2 Results and Discussion

### 3.2.1 Formation of Cyclometalated (PCP)IrNBE Complexes

Norbornene is a strained cyclic molecule that acts as a hydrogen acceptor for (R-PCP) $\operatorname{IrH}_{n}(\mathrm{R}=\mathrm{H}$ or Me) to give access to the $14 \mathrm{e}^{-}$(R-PCP)Ir species via exchange with the $\pi$-bound species as discussed in Chapter 2. When the norbornene complex is heated at $100^{\circ} \mathrm{C}$ for 12 hours, cyclometalated complexes 3-1 and 3-2 are formed in which intramolecular C-H activation of a ${ }^{t}$ butyl group has occurred (Scheme 3.4).

Scheme 3.4 Synthesis of Cyclometalated Norbornene Complexes, 3-1 and 3-2

3-1 R=H
3-2 $R=M e$
The ${ }^{31} \mathrm{P}$ NMR spectra of both complexes show a doublet of doublets, centered at approximately 86 and -20 ppm with a $J_{P P}$ coupling of 230 MHz . The ${ }^{1} \mathrm{H}$ NMR spectra of both complexes clearly indicate the unsymmetrical nature of the complex. The methylene protons attached to the backbone exhibit splitting of the methylene signal into four multiplets ranging from 2.5 to 3.5 ppm , and the ${ }^{t}$ butyl groups are split into three doublets at $1.5,1.3$ and 1.0 ppm . The methyl group signals of the newly created cyclometalated arm are also observed as doublets at approximately 2 and 1 ppm . The ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ NMR support a cyclometalated complex rather than an inserted product, as there is no observed shift for $\mathrm{ArCH}_{2} \mathrm{M}$ protons. Norbornene is presumably the stabilizing ligand, however any attempts to crystallize this complex have proven ineffective and the observance of the NBE proton signals was not successful. 2D gCOSY NMR spectroscopy of 3-2 did not provide any further information as only correlations between the methylene protons were definitively observed.

### 3.2.2 Reaction of Cyclometalated (Me-PCP)IrNBE Complex with CO

Due to $\pi$-backbonding ability, CO is known to stabilize four and five coordinate (PCP)Ir species to give the five or six coordinate CO adducts. ${ }^{18}$ Upon addition of 1 atm CO gas to 3-2, a 3:2 mixture of 4coordinate (Me-PCP)Ir-CO and the cyclometalated inserted product, 3-3, was formed (Scheme 3.5).

Scheme 3.5 Addition of CO to Cyclometalated Complex 3-2

In complex 3-2, the ${ }^{t}$ butyl group which had initially undergone C-H activation has now inserted into the ipso C-Ir bond to form the cyclometalated inserted (Me-PCP)Ir-CO adduct 3-3. This is the first
example of a PCP catalyst that has undergone both insertion and cyclometalation. Previously, examples of phenyl ring insertion into the (PCP) aryl-metal bond via a C-C coupling reaction have been cited, though not for the ligands previously attached to the phosphine arms. ${ }^{2}$

The ${ }^{31} \mathrm{P}$ NMR spectrum of $\mathbf{3 - 3}$ shows two doublets at 89.8 and 5.3 ppm with $J_{P P}=272.8 \mathrm{~Hz}$. A combination of the product crystal structure, recrystallized from a benzene/pentane mixture, and ${ }^{1} \mathrm{H}$ and 2D gCOSY NMR spectroscopy techniques were used to determine the exact structure (Figures 3.5-7, respectively). The crystal structure of $\mathbf{3 - 3}$ shows the Ir-CO is $1.84 \AA$, which is comparably shorter than the Ir-CO bond length in most (PCP)Ir-CO complexes (1.873 $\AA$ ). ${ }^{19}$ The gCOSY NMR indicates correlations between the two cyclometalated methyl groups ( $\mathrm{H} 21-\mathrm{H} 20$ ), between methylene and the cyclometalated methyl protons (H10b-H21), and between the inserted proton and cyclometalated methyl (H1-H20). Interestingly, there is an interaction between the inserted proton and the para methyl protons attached to aryl backbone (H1-H8). These correlations have been indentified on the 2D gCOSY NMR spectrum along with other expected correlations between the ${ }^{t}$ butyl, methylene and aryl protons within the complex. All crystal data and full characterization have been included at the end of the chapter.

Figure 3.5 Crystal Structure of 3-3

Figure 3.6 2D gCOSY NMR Spectrum of 3-3

Figure 3.7 Expanded Region from 0.0-4.0 ppm of 2D gCOSY NMR Spectrum of 3-3

### 3.2.3 Reactions of Cyclometalated Complex, 3-2, with $\mathrm{H}_{2}$ and Ethylene

Reactions were conducted with $\mathrm{H}_{2}$ and ethylene to give some insight into the reactivity of 3-2. (Me-PCP) $\mathrm{IrH}_{4}$ is formed when 3-2 is reacted with hydrogen (Scheme 3.6), which is supported by ${ }^{1} \mathrm{H}$ and ${ }^{31}$ P NMR spectroscopy (see Chapter 2).

Scheme 3.6 Reaction of 3-2 with $\mathrm{H}_{2}$

Norbornane should be observed in the proton spectrum as the byproduct of hydrogenation and ligand elimination, however singlets for the pincer ${ }^{t}$ butyl groups ( $\delta_{\mathrm{H}}=\sim 1.20 \mathrm{ppm}$ ) overlap the signals for norbornane $\left(\delta_{\mathrm{H}}=1.0-1.6 \mathrm{ppm}\right){ }^{20}$ Therefore GC analysis was conducted to isolate and separate the organic products of this reaction. A standard solution of 20 mM norbornene and 40 mM norbornane in $p$-xylene give two signals at a retention time of 4.20 and 4.30 minutes respectively. A GC trace of the reaction mixture also gives similar signals at 4.26 and 4.33 minutes, which could possibly correlate to norbornane.

Table 3.1 Retention Times for the Reaction of 3-2 with $\mathrm{H}_{2}$ to Release Norbornane

| Retention time | Area \% | Assignment |
| :---: | :---: | :---: |
| 0.1 | 23.47 | injection spike |
| 3.43 | 76.213 | $\mathrm{C}_{6} \mathrm{D}_{6}$ |
| 4.26 | 0.037 | norbornane |
| 4.33 | 0.034 | norbornane |
| 5.26 | 0.064 | $p$-xylene |
| 5.31 | 0.131 | $p$-xylene |

The addition of 1 atm of ethylene to $\mathbf{3 - 2}$ gives the ethylene complex as the main product as characterized by NMR spectroscopy (Scheme 3.7). Presumably, norbornene is released during this reaction, but was not confirmed by GC analysis.

Scheme 3.7 Reaction of 3-2 with Ethylene

### 3.2.4 Proposed Mechanisms for the Formation of Cyclometalated Products

The proposed mechanism for the formation of the cyclometalated products 3-1 and 3-2 is detailed in Figure 3.8. The mechanism is most similar to pathway B proposed by Kaska (Figure 3.4) in which C-H activation of the aryl bond is favored versus C-H activation of ${ }^{t}$ butyl followed by attack at the free coordination site. ${ }^{10}$ Starting from the active $14 \mathrm{e}^{-}$species rather than bidentate species $\mathbf{D}$ proposed in Scheme 3.2, the tbutyl arm undergoes C-H activation to form cyclometalated hydride intermediates 3-1a or 3-2a. This intermediate is akin to the seven coordinate $\operatorname{Ir}(\mathrm{V})$ complex proposed in Figure 3.4, however a hydride is located trans to the C-H activated ${ }^{t}$ butyl arm instead of a dihydrogen ligand. Addition of norbornene leads to intermediates 3-1b and 3-2b. Finally, release of $\mathrm{H}_{2}$ gas accompanied by addition of a norbornyl ligand makes the reaction irreversible and allows for isolation of 3-1 and 3-2.

Figure 3.8 Proposed Mechanism for the Formation of 3-1 and 3-2

The addition of CO gas to the cyclometalated products leading to the 4 -coordinate ( $\mathrm{Me}-\mathrm{PCP}$ ) IrCO and cyclometalated inserted product, 3-3, can be explained as follows. Beginning from 3-2, addition of

CO gas leads to formation of the four coordinate CO species via loss of norbornene as has been shown previously. ${ }^{18}$ There are two proposed pathways for the formation of the cyclometalated CO complex. Formation of the six coordinate intermediate species (3-3a) occurs through initial addition of CO followed by elimination of the norbornyl ligand leading to carbene intermediate $\mathbf{3 - 3 b}$; similar intermediates have been documented in the literature. ${ }^{8,21,22}$ The carbene intermediate then undergoes insertion to form the cyclometalated insertion product. Secondarily, coupling of the ${ }^{t}$ butyl arm to the ipso carbon of the aryl ring gives intermediate 3-3c, similar to the reaction proposed by Milstein. After coupling, C-H activation of 33c leads to 3-3d and displacement of the NBE ligand with CO gives 3-3.

Figure 3.9 Proposed Pathways for the Formation of the Cyclometalated Insertion CO product

### 3.2.5 Synthesis of Cyclometalated (Me-PCP)IrCl, 3-4

Upon heating (Me-PCP)IrHCl in the presence of trifluoroacetic acid $\left(\mathrm{CF}_{3} \mathrm{COOH}\right)$ in dichloromethane, a cyclometalated (Me-PCP)IrCl complex (3-4) is generated (Scheme 3.8). This species is analogous to the cyclometalated (POCOP) $\operatorname{IrCl}$ species isolated by Koridze et. al. using the same method.

Scheme 3.8 Synthesis of Cyclometalated (PCP)IrCl Complex, 3-4

Synthesis of 3-4 and cyclometalated (POCOP) IrCl complexes presumably proceeds through a different pathway than those proposed for species 3-1 through 3-3. As discussed in Chapter 2, the $14 \mathrm{e}^{-}$ species is commonly generated by reaction of the dihydride complex with a hydrogen acceptor. ${ }^{23,24}$ Reaction of the (PCP) IrHCl with a base will also successfully generate the active $14 \mathrm{e}^{-}$species. ${ }^{13}$ Under acidic conditions, the $14 \mathrm{e}^{-}$species will most likely not exist. The proposed mechanism for the formation of 3-4, Figure 3.10, starts with protonation of (PCP)IrHCl to form intermediate 3.4a. Elimination of $\mathrm{H}_{2}$ and C-H activation of the ${ }^{t}$ butyl arm allows for formation of 3-4b. Finally, deprotonation regenerates $\mathrm{CH}_{3} \mathrm{COOH}$ and 3-4 is isolated.

Figure 3.10 Potential Mechanism for the Formation of 3-4

### 3.2.6 Synthesis of Cyclometalated (PCP)IrFBF 3 , 3-5

When 3-4 is reacted with $\mathrm{AgBF}_{4}$ in acetone, AgCl is formed as the precipitate and the $\mathrm{BF}_{4}$ counterion is activated giving cyclometalated complex 3-5 (Scheme 3.9). This product was determined by ${ }^{1} \mathrm{H},{ }^{31} \mathrm{P}$, and ${ }^{19} \mathrm{~F}$ NMR spectroscopy. The observation of two signals in the ${ }^{19} \mathrm{~F}$ NMR spectrum, a doublet at -185.9 ppm and a broad singlet at -186.5 ppm , for two different fluorine atoms indicates activation of the $\mathrm{BF}_{4}$ counterion. Presumably

Scheme 3.9 Synthesis of Cyclometalated (PCP)IrFBF 3 Complex, 3-5

### 3.3 Conclusion

The synthesis and characterization of cyclometalated complexes 3-1, 3-2, 3-4, and 3-5 have been reported. The cyclometalated inserted product 3-3 has also been isolated. These complexes represent interesting structural motifs of (PCP)Ir catalysts. The mechanistic pathway for the formation of 3-1 and 3-2 has been proposed and compared to previously cited mechanisms but the main difference is the starting $14 \mathrm{e}^{-}$species. The mechanism for the formation of $\mathbf{3 - 3}$ was postulated based on intermediates $\mathbf{3 - 3} \mathbf{b}$ and $\mathbf{3 -}$ 3c, which have been documented in the literature. Finally, cyclometalated species 3-4 and 3-5 were isolated and characterized using an array of NMR techniques. The acid catalyzed mechanism for the formation of 3-4 was postulated. Overall, more research must be done to understand the synthesis and reactivity of these interesting complexes.

### 3.4 Experimental

General
All reactions were performed under an argon atmosphere using standard Schlenck techniques or in an argon-filled glove box. $\mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{C}_{6} \mathrm{D}_{6}, \mathrm{TBE}$, and $p$-xylene- $d_{10}$ were dried over $\mathrm{Na} / \mathrm{K}$ alloy and collected via vacuum transfer. Norbornene (NBE) was sublimed before use. (PCP)IrNBE and (PCP)IrHCl were synthesized according to literature procedures. ${ }^{23,25,26}$ All other substrates were degassed before entry to
glovebox and used without further purification. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{31} \mathrm{P},{ }^{19} \mathrm{~F}$ NMR spectra were obtained from either a 400 or 500 MHz Varian instrument. The residual peak of the deuterated solvent was used as a reference for all ${ }^{1} \mathrm{H}$ NMR spectra and an internal capillary standard of $\mathrm{PMe}_{3}$ in $p$-xylene- $d_{10}(-62.4 \mathrm{ppm})$ was used to reference ${ }^{31} \mathrm{P}$ NMR chemical shifts. ${ }^{19} \mathrm{~F}$ NMR chemical shifts were referenced by an internal capillary standard of fluorobenzene in $p$-xylene $-d_{l 0}$.

## (PCP)Ir cyclometalated product, 3-1

20 mg norbornene $(0.21 \mathrm{mmol})$ was added to a $p$-xylene- $d_{10}$ solution of $13.0 \mathrm{mg}\left(\mathrm{PCP}^{2}\right) \mathrm{IrH}_{2}(0.022$ mmol ). The solution was heated in a $100{ }^{\circ} \mathrm{C}$ oil bath for 12 hours. The product was characterized in situ. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}$ ): $\delta 86.339\left(\mathrm{~d}, \boldsymbol{J}_{P P}=230.7\right.$ ), -20.311 ( $\mathrm{d}, \boldsymbol{J}_{P P}=230.7$ ). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$ -xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{5 0 0} \mathbf{~ M H z}\right): \delta 6.95(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}-H), 6.75(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ar}-H), 3.45-2.41\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.44\left(\mathrm{~d}, J_{P H}=\right.$ $8.8 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CH}), 2.41\left(\mathrm{~d}, J_{P H}=8.8 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CH}\right) 1.89\left(\mathrm{~d}, 3 \mathrm{H}, \mathrm{Ar}^{2}-\mathrm{CH}_{3}\right), 1.36\left(\mathrm{~d}, 9 \mathrm{H}, \mathrm{P}^{\prime} \mathrm{Bu}\right), 1.25(\mathrm{~d}, 9 \mathrm{H}$, $\left.P^{\prime} B u\right), 1.03(d, 3 H, M e), 0.90\left(d, 9 H, P^{t} B u\right)$.

## (Me-PCP)Ir cyclometalated, 3-2

19.8 mg norbornene ( 0.21 mmol ) was added to a $p$-xylene- $d_{10}$ solution of $13.0 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrH}_{2}$ $(0.022 \mathrm{mmol})$. The solution was heated in a $100^{\circ} \mathrm{C}$ oil bath for 12 hours. The product was characterized in situ. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 86.39\left(\mathrm{~d}, \boldsymbol{J}_{P P}=230.8\right),-20.37\left(\mathrm{~d}, \boldsymbol{J}_{P P}=230.9\right) .{ }^{1} \mathbf{H}$ NMR ( $\boldsymbol{p}$ -xylene- $d_{10}, 400 \mathrm{MHz}$ ): $\delta 6.78$ ( $2 \mathrm{H}, \mathrm{Ar}-H$ ), 3.52-2.75 (m, 4H, CH $\mathrm{C}_{2} \mathrm{P}$ ), $2.42\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.98(\mathrm{~d}, J=$ $14.5 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{Me}), 1.50\left(\mathrm{~d}, J=11.4,9 \mathrm{H}, \mathrm{P}^{\prime} \mathrm{Bu}\right), 1.38\left(\mathrm{~d}, 9 \mathrm{H}, \mathrm{P}^{\prime} \mathrm{Bu}\right), 1.10(\mathrm{~d}, J=11.2,3 \mathrm{H}, \mathrm{Me}), 1.01(\mathrm{~d}, J=$ $\left.1.6,9 \mathrm{H}, \mathrm{P}^{\prime} \mathrm{Bu}\right)$.

## (Me-PCP)Ir-CO cyclometalated, 3-3

1 atm CO gas was added to a $p$-xylene- $d_{10}$ solution of 13.0 mg 3-2 ( 0.022 mmol ). Upon mixing, the solution immediately turned from red to yellow in color. The 4-coordinate (Me-PCP)Ir-CO and 3-3 were observed in a $3: 1$ ratio by ${ }^{31}$ P NMR spectroscopy. Solvent was removed via vacuum, leaving behind a mixture of products as a powder. Dissolving the powder in pentane gave the 4 -coordinate (Me-PCP)Ir-CO as a yellow liquid and 3-3 as a brown solid. The mixture was filtered and washed with pentane and product 3-3 was crystallized from a benzene/pentane mixture to obtain dark brown crystals. X-ray crystallography refinement and structure parameters are included in Tables 3.2 through 7 . ${ }^{31} \mathbf{P} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{2 0 2 . 3} \mathbf{~ M H z}\right)$ :
$\delta 89.78\left(\mathrm{~d}, \boldsymbol{J}_{P P}=272.9 \mathrm{~Hz}\right), 5.33\left(\mathrm{~d}, J_{P P}=272.8 \mathrm{~Hz}\right) .{ }^{1} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{5 0 0} \mathbf{~ M H z}\right): \delta 7.16\left(\mathrm{~s}, \mathrm{C}_{6} \mathrm{D}_{6}\right), 6.79$ $(\mathrm{s}, 1 \mathrm{H}, \operatorname{Ar}-H), 6.71(\mathrm{~s}, 1 \mathrm{H}, \operatorname{Ar}-H), 3.38\left(\mathrm{dd}, 1 \mathrm{H}, \mathrm{H}_{3}\right), 3.23\left(\mathrm{~m}, 1 \mathrm{H}, \mathrm{H}_{1}\right), 2.85\left(\mathrm{dd}, 1 \mathrm{H}, \mathrm{H}_{2}\right), 2.75(\mathrm{dd}, 1 \mathrm{H}$, $\mathrm{H}_{4}$ ), $2.49(\mathrm{dd}, 1 \mathrm{H}, \mathrm{H}), 2.27\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}^{2}-\mathrm{CH}_{3}\right), 1.98(\mathrm{~d}, 3 \mathrm{H}, \mathrm{Me}), 1.29\left(\mathrm{~d}, 9 \mathrm{H} \text {, single } \mathrm{P}^{t} \mathrm{bu}\right)^{*}$, $1.09(\mathrm{~d}, 3 \mathrm{H}, \mathrm{Me})$, 1.06 ( $9 \mathrm{H}, \mathrm{P}^{t}$ bu), 1.03 ( $9 \mathrm{H}, \mathrm{P}^{t}$ bu). ${ }^{13} \mathbf{C}$ NMR ( $\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{1 2 5 . 6 7} \mathbf{~ M H z ) : ~} \delta 174$ (CO), 138 (C3), 136 (C7), 131 (C2), 127.5 (C5), 123 (C4), 109 (C6), 52 (C9), 47.5 (C10), 37.05 (C15), 34.15 (C11), 29.5 (C8), 27.8 (C12C14), 27.4 (C16-C18), 26.8 (C22), 26.1(dd), 24.7(C23-C25), 24.2, 18.6(s). *single ${ }^{\text {tbutyl }}$ is attached to cyclometalated phosphorous and numbered hydrogen and carbon atoms refer to the assignment within the crystal structure.

## Reaction of 3-2 with $\mathbf{H}_{\mathbf{2}}$

A solution of $13.0 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrH}_{\mathrm{n}}(0.0216 \mathrm{mmol})$ and 26.2 mg NBE $(0.28 \mathrm{mmol})$ in $p$-xylene$d_{10}$ was heated at $100^{\circ} \mathrm{C}$ for 1.5 hours. Excess volatiles and solvent were removed in vacuo, leaving 3-2 as a brown waxy solid. The solid was dissolved in $\mathrm{C}_{6} \mathrm{D}_{6}$ and $\mathrm{H}_{2}$ was bubbled through the solution. The solution changed color from dark brown to red within five minutes. (PCP) $\mathrm{IrH}_{4}$ was confirmed as the major product via ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. ${ }^{27}$ The hydrogenation of norbornane was confirmed via GC analysis, utilizing a Varian 430 GC.

## Reaction of 3-2 with ethylene

A solution of $13.0 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrH}_{\mathrm{n}}(0.0216 \mathrm{mmol})$ and 19.8 mg NBE $(0.21 \mathrm{mmol})$ in $p$-xylene$d_{10}$ was heated at $100^{\circ} \mathrm{C}$ for 1.5 hours to synthesize 3-2 in situ. After degassing, 1 atm ethylene was added to the solution. The solution became yellow brown upon thawing and mixing. (PCP)Ir-ethylene was formed in quantitative yield as confirmed by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. ${ }^{28}$

## (Me-PCP)IrCl cyclometalated, 3-4

To a solution of $15.5 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrHCl}(0.024 \mathrm{mmol})$ in benzene, $60 \mu \mathrm{~L} \mathrm{CF}_{3} \mathrm{COOH}(0.78$ mmol ) was added. The solution was heated in a $90^{\circ} \mathrm{C}$ oil bath for 3 days under a constant flow of argon. The product was isolated in quantitative yield. ${ }^{31} \mathbf{P}$ NMR ( $\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 48.77$ (d, $J_{P P}=345.2 \mathrm{~Hz}$ ), $6.25\left(\mathrm{~d}, J_{P P}=344.9 \mathrm{~Hz}\right) .{ }^{1} \mathbf{H}$ NMR ( $\left.\mathbf{C}_{6} \mathbf{D}_{6}, 400 \mathbf{~ M H z}\right): \delta 6.95(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 3.418(\mathrm{bs}, 1 \mathrm{H}, \mathrm{CH}), 3.14-3.02$ $\left(\mathrm{m}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.39\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}^{2}-\mathrm{CH}_{3}\right), 2.16(\mathrm{~m}, 1 \mathrm{H}, \mathrm{C} H), 1.44\left(\mathrm{~d}, J=13.2 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{3}\right), 1.31(\mathrm{~d}, J=12.8$
$\left.\mathrm{Hz}, 3 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu},\right), 1.16\left(\mathrm{~d}, J=12.8 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.10\left(\mathrm{~d}, J=12.4 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu},\right), 0.70(\mathrm{~d}, J=12.8 \mathrm{~Hz}, 3 \mathrm{H}$, $\mathrm{CH}_{3}$ ).

## (Me-PCP) IrFBF $_{3}$ cyclometalated, 3-5

To a solution of 15.1 mg 3-4 $(0.024 \mathrm{mmol})$ in acetone, $2.5 \mu \mathrm{~L} \mathrm{NH}_{4} \mathrm{OH}(0.063 \mathrm{mmol})$ was added. The solution was transferred to a vial containing 4.8 mg AgBF 4 ( 0.025 mmol ). The solution turned from yellow to dark brown. AgCl precipitates as a dark grey powder within 5 minutes. The solution was washed with acetone to remove AgCl as a solid and volatiles were removed in vacuo, leaving behind the product as an orange powder. ${ }^{\mathbf{3 1}} \mathbf{P} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 50.01\left(\mathrm{~d}, J_{P P}=330.8 \mathrm{~Hz}\right), 4.13\left(\mathrm{~d}, \boldsymbol{J}_{P P}=\right.$ $330.8 \mathrm{~Hz}) .{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\left.\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, 400 \mathrm{MHz}\right): \delta 6.95(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-H), 6.88(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-H), 3.00\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.28$ $\left(\mathrm{m}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 1.51\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.19\left(\mathrm{~d}, J=13.6 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.12\left(\mathrm{~d}, J=14 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 0.99(\mathrm{~d}$, $\left.J=13.6 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 0.75\left(\mathrm{~d}, J=16.8 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{3}\right), 0.65\left(\mathrm{~d}, J=12.4 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{3}\right) 0.64(\mathrm{~d}, J=12.8 \mathrm{~Hz}$, $\mathrm{IH}, \mathrm{Ir}-\mathrm{C} H), 0.56(\mathrm{~d}, J=13.2 \mathrm{~Hz}, \mathrm{IH}, \mathrm{Ir}-\mathrm{CH}) .{ }^{19} \mathbf{F} \mathbf{N M R}\left(\mathbf{C}_{6} \mathbf{D}_{6}\right): \delta-185.9(\mathrm{~d}),-186.5(\mathrm{bs})$.

## Chapter 4

## Initial Studies on the Reactivity of (Me-PCP)Ir Towards Oxidants

#### Abstract

Transition metals have become easy targets for the selective oxidation of petroleum feedstocks, but the current understanding of these transformations is limited to oxygen activation and binding, the reactivity of oxidants and isolation of a few intermediates. The synthesis and characterization of two (MePCP)Ir oxygen species is detailed via direct reaction with oxygen. A discussion of (Me-PCP)Ir reactivity with different oxidants will follow. For example, reaction with dimethyldioxirane leads to ring opening of DMDO yielding an acetate ligand and reaction with hydrogen peroxide leads to a cyclometalated product. Finally, the efforts to react nitrous oxide with (Me-PCP)Ir are discussed.

### 4.1 Introduction

The selective oxidation of petroleum feedstocks to produce a variety of alcohols, esters, ethers, acids, etc. is one of the foremost challenges in the chemical world today. ${ }^{1,2}$ Not only is the production of these useful chemicals important, but the development of more atom economical routes to these chemical products is also necessary, particularly through incorporation of carbon dioxide synthesized by use of hydrocarbons. ${ }^{3}$ Transition metals have become easy targets for these goals, but the current understanding of these transformations stems from deficient knowledge of the reactivity of oxidants, including oxygen, towards transition metals and limited isolation of reactive intermediates to harness the selectivity of oxygen type complexes in catalytic cycles. ${ }^{4}$

Molecular oxygen has been shown to bind to all transition metals either in a monomeric fashion, through side-on (two oxygens bound to one metal center) or end-on (one oxygen bound to one metal center) binding modes, or in dimeric fashion ( $\mathrm{O}_{2}$ is shared between two metal centers). ${ }^{5}$ One of the most important advances in the field of transition metal oxygen complexes was the discovery of reversible oxygen binding to the square planar iridium (I) complex synthesized by Vaska originally discussed in Chapter 1 (Scheme 4.1). ${ }^{6}$ This was the first report of side-on binding of $\mathrm{O}_{2}$ to a metal center. Since the synthesis of this complex and the study of its reversible nature, many analogous structures have been isolated.

## Scheme 4.1 Reversible Binding of Oxygen to Vaska’s Complex

In reference to the work presented here, different pincer type complexes have been known to react with oxygen differently. ${ }^{4}$ The insertion of $\mathrm{O}_{2}$ into a $\mathrm{Pd}-\mathrm{H}$ bond of (PCP) PdH yields a $\mathrm{Pd}(\mathrm{II})$ hydroperoxide complex as well as a hydroxide complex in small amounts. ${ }^{4,7}$ This insertion is thought to proceed through direct attack of the oxygen at the $\mathrm{Pd}-\mathrm{H}$ bond. Meanwhile, reaction of the $14 \mathrm{e}^{-}(\mathrm{PCP}) \mathrm{Ir}$ fragment with $\mathrm{O}_{2}$ leads to mono and bis di-oxygen complexes with no evidence of any oxygen insertion into the Ir-H bond. ${ }^{4,8}$ Addition of oxygen to the $16 \mathrm{e}^{-}(\mathrm{PCP}) \mathrm{IrH}_{2}$ complex leads to observation of a dihydride dioxygen complex, suggesting $\mathrm{O}_{2}$ coordinates to the open site then promotes reductive elimination of $\mathrm{H}_{2}$ to form the mono bis-
oxygen complex. The addition of $\mathrm{O}_{2}$ is found to be reversible as addition of hydrogen leads to elimination of water and formation of (PCP) $\operatorname{IrH}_{4}$ (the oxidative addition of water to the active $14 \mathrm{e}^{-}$(PCP)Ir complex and formation of the hydrido hydroxyl species was previously discussed in Chapter 2). ${ }^{9}$

Even though $\mathrm{O}_{2}$ is an attractive oxidant to utilize in terms of cost and accessibility, the formation of these bis di-oxygen complexes are generally very stable and oftentimes characterized as decomposition of the catalyst as no further transformations are observed. Conversely, O-O bond breakage, leading to a highly reactive metal-oxo complex in which a single oxygen is bound to a metal center, is quite difficult due to the high energy barrier and very rare. Generation of these metal-oxo complexes must proceed through alternative methods. Metal oxo complexes can lead to functionalization of many substrates and have been proposed as the active species in many systems. ${ }^{2}$ Terminal oxo complexes for early transition metals are quite common and very stable. ${ }^{10}$ However, for late transition metals, terminal oxo complexes are much rarer though the possibility of alkane functionalization seems more probable in the cases of late transition metal complexes due to their strong abilities for C-H activation. In fact, there exists an "oxo wall" in which late transition metal ( $\mathrm{d}^{4}$ and above) oxo complexes cannot exist in an octahedral environment. Terminal oxo ligands are excellent $\pi$ donors as well as hard Lewis acids and require empty $\pi$ orbitals for bonding, therefore the hard early transition metals with low oxidations states and low $d$-electron counts are preferred in order to satisfy the needs of a stable oxo complex. Oftentimes, in attempts to stabilize the oxo ligand, bridging will occur allowing for multiple metal centers to fulfill the electron orbital needs of the oxygen.

Various attempts have been used to synthesize these oxo complexes, including an array of oxidants (e.g. nitrous oxides (and derivatives), water, peroxides, etc.). The first reported example of a late transition metal oxo complex in the platinum group was a trimesityl iridium complex in which the oxo ligand is stabilized by a tetrahedral environment, minimizing the interactions between the iridium $d$ electrons and the oxo ligand. ${ }^{11}$ This was accomplished via a quantitative reaction with $\operatorname{Ir}(\operatorname{mes})_{3}$ and trimethylamine N -oxide $\left(\mathrm{Me}_{3} \mathrm{NO}, \mathrm{TMAO}\right)$ in diethylether. In relation to pincer type complexes, a dinuclear $\mu$-oxo $\mathrm{PC}_{\text {sp2 }} \mathrm{P}$ iridium complex, in which one oxygen bridges two iridium centers was synthesized starting from the hydroxide derivative. ${ }^{12}$ A terminal cationic $\mathrm{Pt}(\mathrm{IV})$ oxo complex was synthesized via reaction of a
cationic (PCN)Pt(acetone) complex with dimethyldioxirane (DMDO, Scheme 4.2). ${ }^{13-15}$ DMDO is a cyclic peroxide prepared in acetone and is the most common oxidant to rapidly oxidize alkenes. ${ }^{16-18}$

Scheme 4.2 Reaction of Cationic (PCN)Pt Pincer Complex with DMDO

Little is known of the reactivity of nitrous oxide as an oxidant. $\mathrm{N}_{2} \mathrm{O}$ is a poor ligand for transition metals because of its weak $\sigma$-donating and $\pi$-accepting abilities. ${ }^{19}$ The molecule has a number of binding motifs as it can bind end-on through $\eta^{1}$-oxygen or nitrogen, though it also has $\eta^{2}$ and $\eta^{3}$ modes as well. Generally, reactions with $\mathrm{N}_{2} \mathrm{O}$ and transition metals can be summarized into three categories: as an oxo transfer in which $\mathrm{N}_{2}$ gas is released, an oxo or $\mathrm{N}_{2} \mathrm{O}$ insertion into a metal-alkyl or hydride bond, and $\mathrm{N}-\mathrm{N}$ bond scission. Recently, Caulton and coworkers reported a (PNP)Rh species ( $\left.\mathrm{PNP}=\left({ }^{t} \mathrm{Bu}_{2} \mathrm{PCH}_{2} \mathrm{SiMe}_{2}\right)_{2} \mathrm{~N}\right)$ that undergoes oxidation by $\mathrm{N}_{2} \mathrm{O}$ to yield the ( PNP ) $\mathrm{RhN}_{2}$ species and a proposed terminal oxo species as an intermediate decomposing to a hydroxide species at room temperature. ${ }^{20,21}$ The synthesis of the terminal oxo species is supported by DFT calculations and various spectroscopic techniques.

One of the advantages of using $\mathrm{H}_{2} \mathrm{O}_{2}$ as an oxidant is the mild byproducts created upon decomposition (either $\mathrm{H}_{2} \mathrm{O}$ or $\mathrm{H}_{2}$ ). De Bruin published the first example of the oxidation of rhodium and iridium olefin complexes utilizing hydrogen peroxide. ${ }^{22}$ A series of hydroxo and oxo species were proposed as intermediates in the DFT calculated mechanism. ${ }^{23}$ Hydrogen peroxide can also be thought of as an intermediate in the water oxidation cycle. Milstein et. al. proposed an approach to a catalytic cycle in which a (PNN)Ru complex activates water to form a dihydroxo complex and hydrogen, irradiation releases hydrogen peroxide, which decomposes to dioxygen and water, and addition of water regenerates the active catalyst to restart the cycle. ${ }^{24}$

This chapter will focus on introductory experiments conducted between (Me-PCP)Ir and different oxidants. Similar to the parent (PCP)Ir complex, the synthesis of mono and bis di-oxygen (Me-PCP)Ir complexes are detailed. A reaction with DMDO leads to ring opening of DMDO to form a (Me-

PCP)Ir(acetate) complex. Next, reaction with hydrogen peroxide leads to the mono oxygen complex as well as a cyclometalated product, similar to those described in Chapter 3. The characterization of this cyclometalated oxygen complex along with a six coordinate cyclometalated CO adduct is discussed. Finally, efforts to react nitrous oxide with (Me-PCP)Ir close this chapter.

### 4.2 Results and Discussion

### 4.2.1 Isolation of the (Me-PCP)Ir Dioxygen Complexes

When oxygen is bubbled through a solution of (Me-PCP) $\operatorname{IrH}_{n}$ in $\mathrm{C}_{6} \mathrm{D}_{6}, \mathbf{4 - 1}$ and 4-2 are isolated in approximately 3:2 ratio (Scheme 4.3). ${ }^{25}$ Both of these complexes have similar NMR spectral characteristics to each other as well as to the parent bis oxygen complexes. Two peaks at 46.8 and 28.7 ppm are observed in the ${ }^{31} \mathrm{P}$ NMR spectrum for the mono and bis di-oxygen complexes, respectively. The only difference in the ${ }^{1} \mathrm{H}$ NMR spectra between the (Me-PCP) Ir and parent (PCP)Ir bis di-oxygen complexes is the inclusion of the para methyl shift observed as a singlet at 3.5 and 3.3 ppm for $\mathbf{4 - 1}$ and $\mathbf{4 - 2}$, respectively.

Scheme 4.3 Reaction Between the (Me-PCP) $\mathrm{IrH}_{\mathrm{n}}$ and $\mathrm{O}_{2}$

4.2.2 Reaction with DMDO, TMAO, Acetone, and $\mathrm{H}_{2} \mathrm{O}_{2}$

When (Me-PCP) $\mathrm{IrH}_{\mathrm{n}}$ is reacted with DMDO in acetone and $p$-xylene- $d_{10}$, the major product for the reaction is the $(\mathrm{Me}-\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})\left(\mathrm{OCOCH}_{3}\right)$ complex (4-3) and ethane, as determined by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy (Scheme 4.4). To achieve mass balance, for every 1 mol of iridium, 0.5 mol of ethane is produced, presumably formed through an iridium assisted $\mathrm{CH}_{3}$ recombination. The overall mechanism is unknown but may proceed through ring opening of DMDO through a Baeyer-Villager type rearrangement occurs to give an acetate ligand. The parent $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})\left(\mathrm{OCOCH}_{3}\right)$ was previously synthesized by reacting (PCP)Ir-TBE complex with ethyl acetate to produce $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})\left(\mathrm{OCOCH}_{3}\right)$ and ethane. ${ }^{26,27}$

Scheme 4.4 Reaction of (Me-PCP) $\mathrm{IrH}_{4}$ with DMDO

If the (Me-PCP)Ir fragment is reacted with acetone alone an unstable complex (PCP)Ir(acetone) complex (4-4) is formed (Scheme 4.5). The ${ }^{31} \mathrm{P}$ NMR spectrum shows a broad signal at approximately 68 ppm for species 4-4, as well as a signal for the vinyl hydride (discussed in Chapter 2). The ${ }^{1} \mathrm{H}$ NMR spectrum shows a very broad signal at approximately -37 ppm for the $\mathrm{Ir}-\mathrm{H}$ of this complex, unfortunately, no other ${ }^{1} \mathrm{H}$ NMR signals were distinguishable. Complex $4-4$ is similar in nature to an intermediate proposed by Milstein in which acetone undergoes initial O-coordination to (PNP)IrCOE (COE = cyclooctene) followed by $\mathrm{C}-\mathrm{H}$ activation and proton migration to the PNP backbone to form a (PNP)Ir(acetone) complex. ${ }^{28}$ Over time, the broad peak observed at 69 ppm in the ${ }^{31} \mathrm{P}$ NMR spectrum fades into the noise and impurities become the major signals observed. It can be concluded that acetone is very labile and does not bind tightly to (Me-PCP)Ir, similar to other labile ligands (see Chapters 2 and 5).

## Scheme 4.5 Addition of Acetone to (PCP)IrTBE Complex

As in the case of the trimesityliridium oxo species reported by Wilkinson, the (Me-PCP)Ir fragment was reacted with TMAO in $p$-xylene- $d_{10}$. This reaction was not clean and no major species were detectable by ${ }^{31} \mathrm{P}$ NMR spectroscopy. Presumably, low solubility of TMAO in $p$-xylene leads to a slow and/or incomplete reaction.

Upon addition of hydrogen peroxide to the $14 \mathrm{e}^{-}(\mathrm{Me}-\mathrm{PCP}) \mathrm{Ir}$ species, the monomeric dioxygen species 4-1 is observed as the major product, supported by ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ NMR spectroscopy (Scheme 4.6). It would seem hydrogen is generated via dehydrogenation of $\mathrm{H}_{2} \mathrm{O}_{2}$, but as no free hydrogen gas is observed
by NMR, hydrogenation of norbornene to form norbornane most likely occurs. It is also noted that low solubility of $\mathrm{H}_{2}$ in different solvents could contribute to the lack of free $\mathrm{H}_{2}$ observed by NMR.

Scheme 4.6 Reaction of $\mathrm{H}_{2} \mathrm{O}_{2}$ with (Me-PCP)IrNBE Complex

### 4.2.3 Cyclometalation in the Presence of Oxidants

Leaving the reaction mixture of Scheme 4.6 at room temperature for 24 hours or more, complex 45 is synthesized in situ (Scheme 4.7). Complex 4-5 exhibits spectroscopic data similar to the cyclometalated complexes discussed in Chapter 3. Two sets of doublets are observed at 44.6 and 3.5 ppm in the ${ }^{31} \mathrm{P}$ NMR spectrum with $J_{P P}=349 \mathrm{~Hz}$. The methylene protons attached to the backbone exhibit splitting of the methylene signal into four multiplets ranging from 3.07 to 3.15 ppm . Meanwhile, the ${ }^{t}$ butyl groups are distinctively split into three doublets at $1.36,1.19$ and 1.13 ppm which each integrate to 9 protons. The methyl group signals of the newly created cyclometalated arm are also observed as doublets at 1.5 and 0.73 ppm . Most likely, a hydroxide ligand stabilizes this five coordinate species as no hydride is observed in the hydride region of the ${ }^{1} \mathrm{H}$ NMR spectrum. Caulton also proposed a cyclometalated hydroxide product upon deoxygenation of (PNP)Rh with $\mathrm{N}_{2} \mathrm{O} .{ }^{20}$ The hydroxide proton in Caulton's complex was observed as a signal at $\delta=-3.0 \mathrm{ppm}$. Unfortunately, no hydroxide shift was observed for 4-5. As hydroxide ${ }^{1} \mathrm{H}$ NMR signals are often weak and or broad, the lack of observed hydroxide signal does not negate its presence. ${ }^{29}$ Complex 4-5 can also be generated via 4-1 by reaction of (Me-PCP)IrNBE with gaseous $\mathrm{O}_{2}$ rather than reaction with $\mathrm{H}_{2} \mathrm{O}_{2}$.

Scheme 4.7 Conversion of (Me-PCP) $\mathrm{IrO}_{2}$ into Cyclometalated Hydroxide Product 4-5

While data in Chapter 3 demonstrated that addition of CO led to an interesting cyclometalated insertion product, in this case addition of CO leads to six coordinate species 4-6 (Scheme 4.8). A doublet of doublets centered at 46 and -19 ppm are observed in the ${ }^{31} \mathrm{P}$ NMR spectrum in which $J_{P P}=315 \mathrm{~Hz}$. Again, the ${ }^{t}$ butyl groups are distinctively split into three doublets at $1.27,1.18$, and 1.08 ppm which each integrate to 9 protons and the methyl group signals of the cyclometalated arm are observed as doublets at 1.55 and 0.95 ppm . Unfortunately no hydroxide shift was observed for 4-6 either.

Scheme 4.8 Addition of CO to Cyclometalated Hydroxyl Species

### 4.2.4 Reaction with $\mathrm{N}_{2} \mathrm{O}$

When the $14 \mathrm{e}^{-}(\mathrm{Me}-\mathrm{PCP})$ Ir fragment is reacted with $0.5 \mathrm{~atm} \mathrm{~N}_{2} \mathrm{O}$, the $\mathrm{N}_{2}$ monomer species is formed in quantitative yield as confirmed by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy (Scheme 4.9).

Scheme 4.9 Reaction of (Me-PCP)Ir with $\mathrm{N}_{2} \mathrm{O}$

The major question has been the fate of the oxygen atom and multiple studies were undertaken to ascertain its outcome. Due to the absence of other phosphorous signals in ${ }^{31} \mathrm{P}$ NMR spectra and the
quantitative formation of ( $\mathrm{Me}-\mathrm{PCP}) \mathrm{IrN}_{2}$, it can be concluded that formation of a paramagnetic terminal oxo species or a phosphine oxide did not occur. If $\mathrm{O}_{2}$ gas was formed via $\mathrm{N}-\mathrm{O}$ bond scission the formation of 4-1 would be observed by ${ }^{31} \mathrm{P}$ NMR spectroscopy, but this is not the case. Independent experiments determined (Me-PCP) $\operatorname{IrN}_{2}$ in the presence of either air or $\mathrm{O}_{2}$ gas leads to displacement of the $\mathrm{N}_{2}$ ligand generating 4-1 quantitatively. If oxidation of TBE occurred, an alcohol, epoxide, or ketone would be observed. Alternatively, hydride abstraction and subsequent dimerization of $p$-xylene would form 1,2-di-ptolylethane and water. However, both ${ }^{1} \mathrm{H}$ NMR spectroscopy and GC analysis of the reaction mixture show no formation of new products (Tables 6.1 and 6.2).

Table 4.1 GC Data of Reaction Before Addition of $\mathrm{N}_{2} \mathrm{O}$

| Peak | Retention Time | Area \% |
| :---: | :---: | :---: |
| 1 | 2.34 | 2.472 |
| 2 | 2.38 | 0.372 |
| 3 | 2.44 | 0.095 |
| 4 | 2.61 | 0.020 |
| 5 | 3.17 | 0.087 |
| 6 | 3.28 | 0.031 |
| 7 | 3.43 | 0.033 |
| 8 | 3.88 | 96.845 |
| 9 | 3.98 | 0.045 |

Table 4.2 GC Data for the Reaction After Addition of $\mathrm{N}_{2} \mathrm{O}$

| Peak | Retention Time | Area \% |
| :---: | :---: | :---: |
| 1 | 2.35 | 2.186 |
| 2 | 2.39 | 0.363 |
| 3 | 2.45 | 0.103 |
| 4 | 3.18 | 0.084 |
| 5 | 3.29 | 0.030 |
| 6 | 3.44 | 0.032 |
| 7 | 3.88 | 97.149 |
| 8 | 3.99 | 0.052 |

Finally, mass spectrometry analysis was conducted to assess the purity of the $\mathrm{N}_{2} \mathrm{O} . \mathrm{N}_{2} \mathrm{O}$ when ionized will generate $\mathrm{N}^{+}, \mathrm{O}^{+}, \mathrm{NO}^{+}, \mathrm{N}_{2}^{+}, \mathrm{O}_{2}^{+}$and $\mathrm{N}_{2} \mathrm{O}^{+}$ions, whereas $\mathrm{N}_{2}$ will generate $\mathrm{N}^{+}$and $\mathrm{N}_{2}{ }^{+}$ions. At room temperature, the mass spectrum shows peaks for all six ions for $\mathrm{N}_{2} \mathrm{O}$; however the peak area ratios for $\mathrm{N}_{2}{ }^{+}$at $28 \mathrm{~m} / \mathrm{z}$ versus $\mathrm{NO}^{+}$at $30 \mathrm{~m} / \mathrm{z}$ do not match the $1: 3$ ratio reported in the literature (Figure 4.1). ${ }^{30}$ The
observed ratio of $\mathrm{N}_{2}^{+}: \mathrm{NO}^{+}$is approximately 4:3, more consistent with a spectrum of $\mathrm{N}_{2} \mathrm{O}$ plus $\mathrm{N}_{2}$. Based on these results, it can be concluded that (PCP)Ir is much more reactive towards $\mathrm{N}_{2}$ then $\mathrm{N}_{2} \mathrm{O}$ and, hence, addition of $\mathrm{N}_{2}$ is observed rather than any transformation with $\mathrm{N}_{2} \mathrm{O}$.

Figure 4.1 Room Temperature Mass Spectrum of $\mathrm{N}_{2} \mathrm{O}$

### 4.3 Summary

As expected addition of $\mathrm{O}_{2}$ to (Me-PCP)Ir leads to mono and bis di-oxygen complexes 4-1 and 42, which are similar to the parent bis oxygen complexes. Reaction with DMDO leads to the previously synthesized $(\mathrm{Me}-\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})\left(\mathrm{OCOCH}_{3}\right)$ complex (4-3) and ethane, however the overall mechanism for this transformation is unknown. Addition of hydrogen peroxide yields species 4-1 via dehydrogenation of $\mathrm{H}_{2} \mathrm{O}_{2}$ and further reaction of 4-1 leads to an unexpected cyclometalation generating 4-5. Finally, when the $14 \mathrm{e}^{-}$ (Me-PCP)Ir fragment is reacted with $\mathrm{N}_{2} \mathrm{O}$, the $\mathrm{N}_{2}$ monomer species is formed quantitatively. However, it was discovered via mass spectrometry that the purity of the $\mathrm{N}_{2} \mathrm{O}$ reactant was compromised by $\mathrm{N}_{2}$ leading to the conclusion that that (PCP)Ir is much more reactive towards $\mathrm{N}_{2}$ than $\mathrm{N}_{2} \mathrm{O}$. The reactions discussed
here lead to some initial studies with different oxidants, but more work is needed to understand the reactivity of pincer complexes in this interesting field.

### 4.4 Experimental

## General

All reactions were performed under an argon atmosphere using standard Schlenck techniques or in an argon-filled glove box. $\mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{C}_{6} \mathrm{D}_{6}$, TBE, and $p$-xylene- $d_{10}$ were dried over $\mathrm{Na} / \mathrm{K}$ alloy and collected via vacuum transfer. Norbornene (NBE) was sublimed before use. DMDO was synthesized as an acetone solution according the literature procedure, dried over molecular sieves and degassed prior to use (provided by the Lawrence Williams research group). ${ }^{31}$ The concentration of DMDO solutions was determined via titration with $\mathrm{PPh}_{3}$ as 0.202 M. $\mathrm{H}_{2} \mathrm{O}_{2}$ was purchased as $50 \mathrm{wt} \%$ solution from Sigma-Aldrich. $\mathrm{N}_{2} \mathrm{O}$ was purchased as $98 \%$ purity grade gas from Aldrich. The mass spectrometry experiments were done with the assistance from the Jane Hinch Group. All other substrates were degassed before entry to glovebox and used without further purification. ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ NMR spectra were obtained from either a 400 or 500 MHz Varian instrument. The residual peak of the deuterated solvent was used as a reference for all ${ }^{1} \mathrm{H}$ NMR spectra and an internal capillary standard of $\mathrm{PMe}_{3}$ in $p$-xylene- $d_{10}(-62.4 \mathrm{ppm})$ was used to reference ${ }^{31} \mathrm{P}$ NMR chemical shifts.

## (Me-PCP) $\operatorname{IrO}_{2}$ and $(\mathrm{Me}-\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{O}_{2}\right)_{2}, 4-1$ and 4-2

Oxygen was bubbled through a solution of $10.3 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{2}(17.1 \mu \mathrm{~mol})$ in $\mathrm{C}_{6} \mathrm{D}_{6}$. Solution immediately changed from a deep red to green. Complexes were characterized in situ. (Me-PCP)IrO $\mathbf{2}$, 41: ${ }^{31} \mathbf{P}$ NMR $\left(\mathbf{C}_{6} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9 M H z}\right): \delta 46.8\left(\mathrm{~s},(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrO}_{2}\right) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{4 0 0} \mathbf{M H z}\right): \delta 6.87(\mathrm{~s}, 2 \mathrm{H}$, Ar-H), $3.49\left(\mathrm{vt}, J=4 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.36\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.35(\mathrm{t}, J=6 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P} \mathrm{t} \mathrm{bu})$. (Me$\mathbf{P C P}) \operatorname{Ir}\left(\mathbf{O}_{\mathbf{2}}\right)_{\mathbf{2}}, \mathbf{4 - 2 :}{ }^{\mathbf{3 1}} \mathbf{P} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9 M H z}\right): \delta 28.7\left(\mathrm{~s},(\mathrm{Me}-\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{O}_{2}\right)_{2}\right) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{4 0 0}\right.$ MHz): $\delta 6.79(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.29\left(\mathrm{vt}, J=4 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.31\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.21(\mathrm{t}, J=8 \mathrm{~Hz}, 36 \mathrm{H}$, $\left.P^{t} b u\right)$.

## (Me-PCP)Ir(acetone), 4-3

To a solution of $13.0 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(21.6 \mu \mathrm{~mol})$ in $p$-xylene- $d_{10}, 25 \mu \mathrm{~L}$ TBE $(194 \mu \mathrm{~mol})$ was added to generate the vinyl hydride complex in situ. Addition of $20 \mu \mathrm{~L}$ acetone ( $272 \mu \mathrm{~mol}$ ) yielded
complex 4-3, characterized in situ. ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 68.4$ (bs). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$ -xylene- $\left.\boldsymbol{d}_{10}, 400 \mathrm{MHz}\right): \delta-37.10(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ir}-H)$.

## (Me-PCP) $\operatorname{Ir}(\mathbf{H})\left(\mathrm{OCOCH}_{3}\right), 4-4$

To a solution of $9.5 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrHn}(15.8 \mu \mathrm{~mol})$ in $p$-xylene- $d_{10}, 0.5 \mathrm{~mL}$ DMDO solution (101 $\mu \mathrm{mol})$ was added. The solution instantly turned from dark red to red. The excess volatiles and solvent are removed in vacuo to leave behind a red powder. The powder was washed with hexanes. Hexanes were
 $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9 M H z}\right): \delta 60.23(\mathrm{~d}, J=10.4 \mathrm{~Hz}) .{ }^{\mathbf{3 1}} \mathbf{P} \mathbf{N M R}\left(\mathbf{C D}_{\mathbf{2}} \mathbf{C l}_{\mathbf{2}}, \mathbf{1 6 1 . 9 M H z}\right): \delta 59.7(\mathrm{~d}, J=12 \mathrm{~Hz}) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}$ (p-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, 400 \mathrm{MHz}\right): \delta 6.52(\mathrm{~s}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.07\left(\mathrm{~d}\right.$ of $\left.\mathrm{vt}, J_{P H}=3.3 \mathrm{~Hz}, J_{H H}=17.2 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.82$ $\left(\mathrm{d}\right.$ of $\left.\mathrm{vt}, J_{P H}=4.2 \mathrm{~Hz}, J_{H H}=16.8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right)$, methyl not visible, $1.95(\mathrm{~s}, 3 \mathrm{H}$, acetate $), 1.23\left(\mathrm{t}, J_{H H}=6.2\right.$ $\left.\mathrm{Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{bu}\right), 1.16\left(\mathrm{t}, J_{H H}=6.4 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{\mathrm{t}} \mathrm{bu}\right),-30.7\left(\mathrm{t}, J_{H H}=13.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ir}-H\right) .{ }^{1} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{6} \mathbf{D}_{6}, 400\right.$ $\mathrm{MHz}): \delta 6.61(\mathrm{bs}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.10\left(\mathrm{~d}\right.$ of vt, $\left.J_{P H}=3.3 \mathrm{~Hz}, J_{H H}=16.8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.84\left(\mathrm{~d}\right.$ of vt, $J_{P H}$ $\left.=4.0 \mathrm{~Hz}, J_{\mathrm{HH}}=17.2 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.28\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.81(\mathrm{~s}, 3 \mathrm{H}$, acetate $), 1.27\left(\mathrm{t}, J_{H H}=6.4 \mathrm{~Hz}\right.$, $\left.18 \mathrm{H}, \mathrm{P}^{t} \mathrm{bu}\right), 1.18\left(\mathrm{t}, J_{H H}=6.4 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{bu}\right),-30.07\left(\mathrm{t}, J_{H H}=13.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ir}-H\right) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{C D}_{\mathbf{2}} \mathbf{C l}_{\mathbf{2}}, 400\right.$ $\mathrm{MHz}): \delta 6.65(\mathrm{bs}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.20\left(\mathrm{~d}\right.$ of vt, $\left.J_{P H}=3.6 \mathrm{~Hz}, J_{H H}=17.2 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.90\left(\mathrm{~d}\right.$ of vt, $J_{P H}=4$ $\left.\mathrm{Hz}, J_{\mathrm{HH}}=17.2 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.12\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-\mathrm{CH}_{3}\right), 1.80(\mathrm{~s}, 3 \mathrm{H}$, acetate $), 1.35\left(\mathrm{t}, J_{H H}=6.4 \mathrm{~Hz}, 18 \mathrm{H}\right.$, $\left.\mathrm{P}^{t} \mathrm{bu}\right), 1.28\left(\mathrm{t}, J_{H H}=6.4,18 \mathrm{H}, \mathrm{P}^{t} \mathrm{bu}\right),-30.4\left(\mathrm{t}, J_{P H}=13.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ir}-H\right)$.

## Reaction of (Me-PCP)Ir with $\mathbf{H}_{\mathbf{2}} \mathrm{O}_{\mathbf{2}}$

To a solution of $12.4 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(20.6 \mu \mathrm{~mol})$ in $p$-xylene- $d_{10}$, excess NBE was added to generate the norbornene complex in situ. Upon addition of $2.4 \mu \mathrm{~L} \mathrm{H}_{2} \mathrm{O}_{2}$ solution ( $42 \mu \mathrm{~mol}$ ), the mixture released hydrogen gas and solution turned a brown green color. Complex 4-1 was observed as the major product by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy.

## (Me-PCP)Ir cyclometalated $\mathbf{O}_{2}$ product, 4-5

Method 1: To a solution of $12.4 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(20.6 \mu \mathrm{~mol})$ in $p$-xylene- $d_{10}$, excess NBE and $2.4 \mu \mathrm{~L} \mathrm{H}_{2} \mathrm{O}_{2}$ solution ( $42 \mu \mathrm{~mol}$ ) were added to generate complex 4-1. Method 2: Oxygen was bubbled through a solution of $11.8 \mathrm{mg}(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{\mathrm{n}}(19.6 \mu \mathrm{~mol})$ with $20 \mu \mathrm{~L}$ NBE $(106 \mu \mathrm{~mol})$ stock solution in $\mathrm{C}_{6} \mathrm{D}_{6}$ and complex 4-1 was generated. The synthesis of $\mathbf{4 - 1}$ was confirmed via NMR spectroscopy and
after 24 hours at room temperature complex $\mathbf{4 - 5}$ was the major species in solution, characterized in situ. ${ }^{31} \mathbf{P} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 44.6\left(\mathrm{~d}, J_{P P}=349.7 \mathrm{~Hz}\right), 3.53\left(\mathrm{~d}, J_{P P}=349.3 \mathrm{~Hz}\right) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, 400\right.$ MHz): $\delta 6.99(\mathrm{~d}, J=18.4 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-H), 3.55(\mathrm{~m}, 1 \mathrm{H}, \mathrm{CH}), 3.15-3.07\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.40(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}-$ $\left.\mathrm{CH}_{3}\right), 2.18(\mathrm{~m}, 1 \mathrm{H}, \mathrm{C} H), 1.51(\mathrm{~d}, J=13.6 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{Me}), 1.36\left(\mathrm{~d}, J=13.6 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.19(\mathrm{~d}, J=12.8$ $\left.\mathrm{Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.13\left(\mathrm{~d}, J=12.8 \mathrm{~Hz}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 0.73\left(\mathrm{~d}, J=12.8 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{3}\right)$.

## (Me-PCP)Ir-CO cyclometalated $\mathrm{O}_{2}$ product, 4-6

Complex 4-5 was prepared, degassed and 1 atm CO was added to J. Young NMR tube. Upon mixing the solution changes color to golden yellow. The excess volatiles and solvent were removed under vacuum, the sample was washed with pentane giving a yellow solid and the product as a yellow solution. The solvent was removed under vacuum, and sample was dissolved in $\mathrm{C}_{6} \mathrm{D}_{6}$ for characterization. ${ }^{31} \mathbf{P} \mathbf{N M R}$ $\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 46.59\left(\mathrm{~d}, J_{P P}=314.98 \mathrm{~Hz}\right),-18.90\left(\mathrm{~d}, J_{P P}=314.98 \mathrm{~Hz}\right) .{ }^{\mathbf{1}} \mathbf{H} \mathbf{N M R}\left(\mathbf{C}_{\mathbf{6}} \mathbf{D}_{\mathbf{6}}, 400\right.$ MHz): $\delta 6.812(\mathrm{~s}, 1 \mathrm{H}, \operatorname{Ar}-H), 6.717(\mathrm{~s}, 1 \mathrm{H}, \mathrm{Ar}-H), 3.257(\mathrm{~d}, 1 \mathrm{H}, \mathrm{CH}), 2.875\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.334(\mathrm{~m}, 1 \mathrm{H}$, $\mathrm{CH}), 2.287\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Ar}^{2} \mathrm{CH}_{3}\right), 1.545(\mathrm{~d}, 3 \mathrm{H}, \mathrm{Me}), 1.273\left(\mathrm{~d}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.179\left(\mathrm{~d}, 9 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right), 1.077(\mathrm{~d}, 9 \mathrm{H}$, $\left.\mathrm{P}^{t} \mathrm{Bu}\right), 0.945(\mathrm{~d}, 3 \mathrm{H}, \mathrm{Me})$.

## Reaction of (Me-PCP)Ir with $\mathbf{N}_{2} \mathrm{O}$

To a solution of 10 mg of $(\mathrm{Me}-\mathrm{PCP}) \mathrm{IrH}_{2}(16.5 \mu \mathrm{~mol})$ mixed with $20 \mu \mathrm{~L}$ TBE $(155 \mu \mathrm{~mol})$ in $p$ -xylene- $d_{l 0}, 0.5 \mathrm{~atm} \mathrm{~N}_{2} \mathrm{O}$ gas was added to the sample. ( $\left.\mathrm{Me}-\mathrm{PCP}\right) \mathrm{IrN}_{2}$ was confirmed as the quantitative product as determined by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. Characterization for (Me-PCP)IrN $\mathrm{N}_{2}$ can be found in Chapter 2.

## GC Experiments

10 mg of $(\mathrm{Me}-\mathrm{PCP}) \operatorname{IrH}_{2}(16.5 \mu \mathrm{~mol})$ was mixed with $20 \mu \mathrm{~L}$ TBE $(155 \mu \mathrm{~mol})$ to generate the $14 \mathrm{e}^{-}$ species in situ. A GC analysis of the solution was collected via Varian 430 GC. 0.5 atm $\mathrm{N}_{2} \mathrm{O}$ gas was added to the sample and secondary GC analysis of the solution was collected.

## Chapter 5

## Determination of Metal-Ligand Bond Energies for (PCP)Ir Complexes

#### Abstract

The determination of bond energies for organic molecules can be easily determined via group increment theory or computational methods. However, the determination of bond energies of transition metal complexes is less reliable as there are no specific trends and computational methods for calculating such large molecules are still developing. The ability to accurately determine bond energies for metal complexes is important for developing new catalysts, determining catalytic intermediates and gaining insight into mechanisms for various transformations. This chapter reports the thermodynamic parameters for the addition of a range of ligands to (PCP)Ir, (PCP) $\mathrm{IrH}_{2}$ and (PCP) $\operatorname{IrHCl}$ complexes. The experimentally determined values are compared to values derived from DFT calculations utilizing a variety of functionals with good agreement.

### 5.1 Introduction

A fundamental understanding of bond energies is critical to understanding modern chemistry. When organic molecules are considered, chemists can easily determine the specific energy of a molecule or reaction via group increment theory ${ }^{1,2}$ or computational methods. For example, the energy of 2methylpentane can be determined by the addition of energies for 3 methyl, 2 methylene, and 1 methine groups (Figure 5.1). Whereas, the energy for the hydrogenation of 2-methylpropene can be determined by subtraction of the enthalpy of products, $-37.43 \mathrm{kcal} / \mathrm{mol}$, from the reactants, $-8.36 \mathrm{kcal} / \mathrm{mol}$, gives the overall enthalpy for the transformation, $-29.07 \mathrm{kcal} / \mathrm{mol}$ (Scheme 5.1).

Figure 5.1 Determination of Enthalpy for 2-methylpentane via Group Increment Theory
~
$\Delta \mathrm{H}_{\mathrm{f}}{ }^{-}=3 \mathrm{CH}_{3}+2 \mathrm{CH}_{2}+1 \mathrm{CH}$
$\Delta H_{f}^{\circ}=3(-10.08)+2(-4.95)+1(-1.90)$
$=-42.04 \mathrm{kcal} / \mathrm{mol}$

## Scheme 5.1 Hydrogenation of 2-methylpropene

The determination of bond energies in transition metal complexes has been an area of equal importance, yet there is a lack of experimental and accurate computational data available. ${ }^{3-17}$ The challenges with determining the thermodynamics of organometallic compounds can be attributed to the complexity, stability and reactivity of the complexes. Different functionals are limited when dealing the larger size of these systems in both accuracy and time, whereas the stability of these complexes in solution, thermally or over time changes as the reaction conditions change leading to the use of a variety of different methods for experimental determination each with its own set of accuracy considerations. Overall, a better understanding of the bond energies of transition metals will enable chemists to design new catalysts, gain insights into mechanisms, and determine intermediates within a catalytic cycle.

This chapter will outline the determination of enthalpy $\left(\Delta \mathrm{H}^{\circ}\right)$, entropy $\left(\Delta \mathrm{S}^{\circ}\right)$, and free energy $\left(\Delta \mathrm{G}^{\circ}\right)$, for the addition of various ligands $(\mathrm{L})$ to $(\mathrm{PCP}) \operatorname{IrHCl}\left(\mathbf{5 - 1}\right.$, Scheme 5.2), (PCP) $\mathrm{IrH}_{2}(\mathbf{5 - 2}),(\mathrm{PCP}) \mathrm{Ir}$
(5-3). The ligands studied undergo $\mathrm{C}, \mathrm{H}, \mathrm{O}, \mathrm{N}, \mathrm{S}$, and P heteroatom additions to the metal center. Secondly, to assess the quality of various computational methods for the determination of metal-ligand binding energies for our catalyst systems, the experimental results are compared to computational values calculated using density functional theory (DFT) ${ }^{18}$ and a range of functionals described below.

### 5.2 Results and Discussion

### 5.2.1 Equilibrium Studies of (PCP)IrHCl, 5-1

Initial addition of ligands ( $\mathrm{L}=$ acetonitrile, isoquinoline, pyridine ( N -type ligands) and $\mathrm{PR}_{3}$ type ligands, $\mathrm{R}_{3}=\mathrm{Et}_{3}, \mathrm{Ph}_{2} \mathrm{Me}, \mathrm{Ph}_{2} \mathrm{OMe}, \mathrm{Me}_{2} \mathrm{Ph}, \mathrm{Me}_{3}, \mathrm{OEt}_{3}, \mathrm{Ph}(\mathrm{OEt})_{2}$, and $\left.\mathrm{Me}(\mathrm{OEt})_{2}\right)$ to 5-1 leads to kinetic product 5-1a in which $L$ coordinates trans to chloride (Scheme 5.3a). This product then undergoes isomerization to give thermodynamic product $\mathbf{5 - 1 b}$, in which $L$ is trans to the aryl ring of the PCP backbone (Scheme 5.3b). The isomerization is due to the steric demand of $L$ when compared to chloride as the preferred orientation of the bulkiest ligand is trans to the phenyl ring of the PCP backbone.

Scheme 5.3 Addition of Ligands $\left(\mathrm{L}=\mathrm{PEt}_{3}\right.$, acetonitrile $\left(\mathrm{CH}_{3} \mathrm{CN}\right), \mathrm{PPh}_{2} \mathrm{Me}$, isoquinoline, pyridine, $\left.\mathrm{PPh}_{2} \mathrm{OMe}, \mathrm{PMe}_{2} \mathrm{Ph}, \mathrm{PMe}_{3}, \mathrm{PPh}(\mathrm{OEt})_{2}, \mathrm{P}(\mathrm{OEt})_{3}, \mathrm{PMe}(\mathrm{OEt})_{2}\right)$ to 5-1 (a) Initial Formation of Kinetic Product, 5-1a (b) Isomerization of 5-1a to 5-1b

The characterization of $\mathbf{5 - 4}$ through $\mathbf{1 4}$, where $\mathrm{L}=\mathrm{PEt}_{3}, \mathbf{5 - 4}$, acetonitrile, 5-5, $\mathrm{PPh}_{2} \mathrm{Me}, \mathbf{5 - 6}$, isoquinoline, 5-7, pyridine, 5-8, $\mathrm{PPh}_{2} \mathrm{OMe}, \mathbf{5 - 9}, \mathrm{PPhMe}_{2}, \mathbf{5 - 1 0}, \mathrm{PMe}_{3}, \mathbf{5 - 1 1}, \mathrm{PPh}(\mathrm{OEt})_{2}, \mathbf{5 - 1 2}, \mathrm{P}(\mathrm{OEt})_{3}, \mathbf{5 -}$ 13, and $\mathrm{PMe}(\mathrm{OEt})_{2}, \mathbf{5 - 1 4}$, and have been included in the experimental section. The X-ray crystal structure of 5-11 has been previously reported. ${ }^{19}$ Isomer $\mathbf{5 - 1}$ a has very broad shifts in the ${ }^{31} \mathrm{P}$ NMR spectrum and the hydride shift in the ${ }^{1} \mathrm{H}$ NMR spectrum is shifted upfield to ca. -10 ppm . The ${ }^{31} \mathrm{P}$ NMR shifts for $\mathbf{5 - 1 b}$ are distinctively split into a doublet for the two phosphorous nuclei in the PCP backbone and a triplet for the $\mathrm{PR}_{3}$ ligand. The hydride shifts for $\mathbf{5} \mathbf{- 1 \mathbf { b }}$ have been shifted upfield to ca. -22 ppm . The $\mathrm{P}-\mathrm{H}$ coupling for the hydride shift of $\mathbf{5 - 1} \mathbf{a}$ is very large $\left(J_{P H}=196\right.$ to 234 Hz$)$ whereas the coupling in $\mathbf{5 - 1 b}$ is much less $\left(J_{P H}\right.$ $=14.5 \mathrm{~Hz})$. In the case where $\mathrm{L}=\mathrm{PPh}_{2} \mathrm{Me}, \mathrm{PPh}_{2} \mathrm{OMe}, \mathrm{PPhMe}_{2}, \mathrm{PEt}_{3}$, or $\mathrm{PMe}_{3}$, only one isomer has been characterized, all NMR spectra are indicative of isomer 5-1b rather than isomer 5-1a as they lack the characteristic hydride shift or coupling constant of 5-1a. Similarly, both 5-1a and 5-1b are observed for $\mathrm{P}(\mathrm{OEt})_{3}, \mathrm{PMe}(\mathrm{OEt})_{2}, \mathrm{PPh}(\mathrm{OEt})_{2}$ ligands due to rapid isomerization. The ligands $\mathrm{PPh}_{2} \mathrm{Me}, \mathrm{PPh}_{2} \mathrm{OMe}$, $\mathrm{PPhMe}_{2}, \mathrm{PEt}_{3}$, or $\mathrm{PMe}_{3}$ are smaller $\mathrm{PR}_{3}$ ligands and therefore isomerize much more quickly, whereas isomerization of the more sterically hindering $\mathrm{P}(\mathrm{OEt})_{3}, \mathrm{PMe}(\mathrm{OEt})_{2}, \mathrm{PPh}(\mathrm{OEt})_{2}$ ligands can be observed on an NMR time scale.

The trans orientation of L to the phenyl ring of the PCP backbone is the more thermodynamically favored isomer and allows for easy elimination of $L$ from the 'pocket' of $\mathbf{5 - 1}$. This easy elimination allows for the equilibrium between $\mathbf{5 - 1}$ and $\mathbf{5 - 1 b}$ to be monitored. Since no intermediates are formed during this process, the binding energy can be directly correlated to the energy of addition for each ligand. For example, upon addition of $\mathrm{PPh}_{2} \mathrm{Me}$ to $\mathbf{1}$ an immediate color change is observed from dark red to pale yellow. At room temperature, in the ${ }^{31} \mathrm{P}$ NMR spectrum, 5-6 is the major product and only a small presence of the $\mathbf{5 - 1}$ is observed. As the temperature is raised from 45 to $105^{\circ} \mathrm{C}$, then the equilibrium shifts towards the reactant side, loss of $\mathrm{PPh}_{2} \mathrm{Me}$ leads to five coordinate $\mathbf{5 - 1}$ becoming the major species in solution. Each species is observable by NMR spectroscopy and so concentration can be determined by integration. The concentrations of each species are then used to determine the equilibrium constant. All equilibrium constants have been included in the experimental section.

If $\mathrm{L}=$ pyridine, acetonitrile $\left(\mathrm{CH}_{3} \mathrm{CN}\right)$, or isoquinoline, isomerization from 5-1a to 5-1b occurs on a much more rapid timescale and only one a broad peak is observed in the NMR spectrum after addition of

L to solution. DFT calculations have been completed for the two isomers of pyridine which conclude that $\mathbf{5 - 1} \mathbf{a}$ is $1-3 \mathrm{kcal} / \mathrm{mol}$ (depending on the functional) more stable then $\mathbf{5 - 1 b}$. As temperature is increased, this peak will shift downfield according to the percentage of $\mathbf{5 - 1}$ and $\mathbf{5 - 1 b}$ in solution. For example, at room temperature, mostly $\mathbf{5 - 8}$ is observed in the ${ }^{31} \mathrm{P}$ NMR spectrum, $\delta_{\mathrm{HClPy}}=46 \mathrm{ppm}$. As the temperature is increased, equilibrium shifts towards $\mathbf{5 - 1}, \delta_{\mathrm{HCl}}=67 \mathrm{ppm}$. The concentration of each species at each temperature is determined by Equation 1 below, where the fraction of each species ( $\mathrm{f}_{\mathrm{HCl}}$ and $\mathrm{f}_{\mathrm{HClL}}$ ) in solution is related to the observed chemical shift $\left(\Delta_{\mathrm{obs}}\right)$ and the chemical shift of the pure species $\left(\delta_{\mathrm{HCl}}\right.$ and $\left.\delta_{\text {HCIL }}\right)$. The fractions can then be converted to concentrations, allowing for determination of the $\mathrm{K}_{\mathrm{eq}}$.

$$
\begin{equation*}
\Delta_{\mathrm{obs}}=\delta_{\mathrm{HCl}} * \mathrm{f}_{\mathrm{HCl}}+\delta_{\mathrm{HClL}} * \mathrm{f}_{\mathrm{HClL}} \tag{1}
\end{equation*}
$$

The change in the free energy, $\Delta \mathrm{G}$, of the overall equilibrium, the $\Delta \mathrm{G}$ of the products minus the $\Delta \mathrm{G}$ of the reactants, will determine the magnitude of the equilibrium constant, $\mathrm{K}_{\mathrm{eq}}$. So if the equilibrium constant can be determined via the ratio of the products to the reactants, then the value of $\Delta \mathrm{G}^{\circ}$ can be determined at each temperature, using Equation 2, where R is the gas constant ( $\mathrm{kcal} / \mathrm{mol} * \mathrm{~K}$ ) and T is temperature (K). ${ }^{20}$

$$
\begin{equation*}
\Delta \mathrm{G}^{\circ}=-\mathrm{RT} \ln \left(\mathrm{~K}_{\mathrm{eq}}\right) \tag{2}
\end{equation*}
$$

A graph of $\Delta \mathrm{G}^{\circ}$ versus temperature (Figure 5.2) will give the $\Delta \mathrm{H}$ as the y -intercept and $\Delta \mathrm{S}$ as the slope of a linear regression (Table 5.1).

Figure 5.2 Graph of $\Delta \mathrm{G}^{\circ}(\mathrm{kcal} / \mathrm{mol})$ versus Temperature ( K ) for the Addition of $\mathrm{L}=\mathrm{PEt}_{3}$ (purple), $\mathrm{CH}_{3} \mathrm{CN}$ (green), $\mathrm{PPh}_{2} \mathrm{Me}$ (red), isoquinoline (orange), and pyridine (blue) to 5-1

This plot is modified from the usual Van 't Hoff plot ( $\ln K_{\text {eq }}$ versus $1 / T$ ) which tends to be used for these types of experiments. The slope of a Van 't Hoff plot will be equal to $-\Delta H / R T$ whereas the $y$ intercept is $\Delta \mathrm{S} / \mathrm{R}$ and so one must multiply the slope or y -intercept by the gas constant (Van 't Hoff Equation shown as Equation 3) to get values for $\Delta \mathrm{H}^{\circ}$ or $\Delta \mathrm{S}^{\circ}$. The $\Delta \mathrm{G}^{\circ}$ versus T plot (Figure 5.2) lends itself to much easier mathematics in order to obtain the desired values. If the data is plotted in the traditional fashion, then values for the fit and resulting values for $\Delta \mathrm{H}^{\circ}, \Delta \mathrm{S}^{\circ}$, and $\Delta \mathrm{G}^{\circ}$ are within experimental error to those reported using the $\Delta \mathrm{G}^{\circ}$ versus T plot.

$$
\begin{equation*}
\ln \left(\mathrm{K}_{\mathrm{eq}}\right)=-\Delta \mathrm{H} / \mathrm{RT}+\Delta \mathrm{S} / \mathrm{R} \tag{3}
\end{equation*}
$$

The thermodynamic values for the addition of $L$ to $\mathbf{5 - 1}$ range, where the most strongly binding ligand is pyridine at $\Delta \mathrm{G}^{\circ}=-6.0(0.4) \mathrm{kcal} / \mathrm{mol}$ whereas the least strongly binding is $\mathrm{PEt}_{3}$ at $\Delta \mathrm{G}^{\circ}=-2.6(0.3)$ $\mathrm{kcal} / \mathrm{mol}$. Surprisingly, $\mathrm{PEt}_{3}$ is less sterically hindered $\left(\right.$ Tolman ${ }^{22}$ cone angle $\left.=132{ }^{\circ}\right)$ in comparison to $\mathrm{PPh}_{2} \mathrm{Me}\left(136^{\circ}\right)$ yet binds much less strongly. The more electronic donating ligand $\mathrm{PEt}_{3}\left(\mathrm{TEP}=2061.7 \mathrm{~cm}^{-}\right.$ ${ }^{1}$ ) binds less strongly then $\mathrm{PPh}_{2} \mathrm{Me}\left(2067.0 \mathrm{~cm}^{-1}\right)$. Overall, no trend can be reliably determined between the Tolman parameters and the binding energies of the $\mathrm{PR}_{3}$ ligands. The $\Delta \mathrm{S}^{\circ}$ values for the $\mathrm{PR}_{3}$ ligands are ca. $-33 \mathrm{kcal} / \mathrm{mol}$, whereas the $\Delta \mathrm{S}^{\circ}$ values are much more negative at ca. $-50 \mathrm{kcal} / \mathrm{mol}$ for the N -type ligands. Since the N-type ligands undergo rapid isomerization from 5-1a to 5-1b (Scheme 5.3b) this may account for the more positive values of entropy that have been determined. The size of the N-type ligands may also be a reason for the observed entropy, as N -type ligands are much less bulky then the $\mathrm{PR}_{3}$ ligands.

The experimentally determined thermodynamic parameters, were compared to a series of computational methods including wB97XD, ${ }^{23}$ B97D, ${ }^{24}$ M06-L, M06, M06-2X, ${ }^{25}$ TPSSh, TPSS, ${ }^{26}$ PBE, ${ }^{27}$ and B3LYP ${ }^{28}$ (Table 5.2). The right hand columns, PBE and B3LYP represent the oldest (before 2000) derived functionals, excluding the M06-L functionals (2008), the rest of the functionals were developed between 2000 and 2008. Overall, any functional that accounts for the long range interactions or Van der Waals forces between atoms, i.e. dispersion (B97D, wB97XD, M06-L, M06-2X, and M06), shows much better agreement with the experimental results, shown in red. This is not surprising as ${ }^{t}$ butyl groups surrounding the metal center make $\mathbf{5 - 1}$ very sterically hindered. With the exception of $\mathrm{L}=$ pyridine all the functionals predict $\Delta \mathrm{S}^{\circ}$ fairly well (within ca. 10 e.u). However, the traditional functionals used in chemistry, PBE and B3LYP, grossly overestimate $\Delta \mathrm{H}^{\circ}$ and $\Delta \mathrm{G}^{\circ}$ for the addition of L to 5-1. The more recently developed functionals M06-L and M06, shown in blue, have much better agreement with the experimentally determined values. ${ }^{29}$ For example, PBE and B3LYP estimate $\Delta \mathrm{G}^{\circ}$ for the addition of $\mathrm{PEt}_{3}$ as 12.5 and $22.6 \mathrm{kcal} / \mathrm{mol}$, 14 and 24 units above the experimental value ( $-2.6 \mathrm{kcal} / \mathrm{mol}$ ), whereas M06-L predicts $\Delta \mathrm{G}^{\circ}$ as $-1.4 \mathrm{kcal} / \mathrm{mol}$, only 1 unit above the experimental. PBE can only reliably predict the binding energy for $\mathbf{5 - 5}$, most likely because $\mathrm{NCCH}_{3}$ is a small ligand and the Van der Waals interactions are minimized.

Interestingly, there is relatively good agreement of the experimentally determined entropy values to the computational entropy values. Oftentimes, calculated entropy values overestimate the experimental values by $50 \%$ and so a trend has been established to multiply the calculated entropies by a factor of 0.5 leading to better agreement. ${ }^{31}$ Any corrections made are an attempt to account for the lack of computer simulations to accurately account for solvation effects. ${ }^{32-35}$ It is important to note that none of these corrections have been applied in this study.

The thermodynamics for the addition of more strongly binding ligands can be determined via exchange equilibria with known ligands (Scheme 5.4). The $\Delta \mathrm{G}^{\circ}$ values, ranging from -2.6 to -13.3 $\mathrm{kcal} / \mathrm{mol}$, for the binding energies of $\mathbf{5 - 1}$ measured via exchange are reported in Table 5.3, and the equilibrium constants for all equilibria are included in the experimental information. The experimental $\Delta \mathrm{G}^{\circ}$ values were compared to computational values determined using the M06-L and PBE functionals. The M06-L functional was chosen because it agrees best with the experimentally determined thermodynamic values for the addition of $\mathrm{L}=\mathrm{PEt}_{3}, \mathrm{CH}_{3} \mathrm{CN}, \mathrm{PPh}_{2} \mathrm{Me}$, isoquinoline and pyridine to $\mathbf{5 - 1}$, whereas the PBE functional was chosen as it is the better of the two functionals which agree least with experimental values (Table 5.2).

Scheme 5.4 Exchange Equilibrium for 5-1

Table 5.3 Experimental $\Delta \mathrm{G}^{\circ}$ Values $(\mathrm{kcal} / \mathrm{mol})$ for the Addition of a Series of Ligands to 5-1 Compared to Computational $\Delta \mathrm{G}^{\circ}$ Values ( $\mathrm{kcal} / \mathrm{mol}$ ) Determined using M06-L and PBE Functionals

The comparison of the experimental values and the computational results are better represented in a graph of the experimental values versus the computational values (Figure 5.3). The experimental values shown as a black line, in which the slope is equal to 1 with a y-intercept of 0 . If the computational values predicted the experimental values exactly, then the slope of these regressions would also be equal to 1 and the $y$-intercept would also be equal to 0 . The regression line for the PBE functional values, in red, overestimated the experimental by a factor of 9.9 units, whereas the regression line for M06-L values, in blue, is only 1.3 units over the experimental values. The root mean square is the average of the differences between the errors. It can be evaluated as the average difference from the computational value to the experimental. The root mean square for values determined via M06-L is $4.3 \mathrm{kcal} / \mathrm{mol}$ while the root mean square for PBE is $9.7 \mathrm{kcal} / \mathrm{mol}$.

Figure 5.3 Graph of Experimental $\Delta \mathrm{G}^{\circ}$ Values versus Computational $\Delta \mathrm{G}^{\circ}$ Values for the Addition of Ligands to 5-1, [Experimental (black), PBE (red), and M06-L (blue), $\left.\Delta \mathrm{G}^{\circ}(\mathrm{kcal} / \mathrm{mol})\right]$.

### 5.2.2 Equilibrium Studies of (PCP)IrH ${ }_{2}$, 5-2

In the case of $\mathbf{5 - 1}, \mathbf{5 - 1 a}$ and $\mathbf{5 - 1 b}$ can be identified and characterized easily when $\mathrm{PR}_{3}$ ligands are studied but rapid isomerization is observed when L is an N -type ligand. A similar scenario is observed in the case of 5-2, in which the kinetic products are isolated for the more sterically bulky ligands, $\mathrm{PPh}_{2} \mathrm{OMe}$, $\mathrm{P}\left(\mathrm{OEt}_{3}\right), \mathrm{PMe}(\mathrm{OEt})_{2}, \mathrm{PPh}(\mathrm{OEt})_{2}$, and the thermodynamic product is isolated for all ligands (Scheme 5.5).

Scheme 5.5 Equilibrium between 5-2 and L

The NMR characterization for $\mathbf{5 - 1 5} \mathbf{- 5 - 3 2}$, in which $\mathrm{L}=2$-picoline, $\mathbf{5 - 1 5}, \mathrm{NH}_{3}, \mathbf{5 - 1 6}$, thiophene, $\mathbf{5 - 1 7}, \mathrm{PPh}_{3}, \mathbf{5 - 1 8}$, dibenzothiophene (DBT), 5-19, $\mathrm{H}_{2}, \mathbf{5 - 2 0}, \mathrm{CH}_{3} \mathrm{CN}, \mathbf{5 - 2 1}, \mathrm{PPh}_{2} \mathrm{Et}, \mathbf{5 - 2 2}$, pyridine, 5-23, isoquinoline, 5-24, $\mathrm{PEt}_{3}, \mathbf{5 - 2 5}, \mathrm{PPh}_{2} \mathrm{Me}, \mathbf{5 - 2 6}, \mathrm{PMe}_{2} \mathrm{Ph}, \mathbf{5 - 2 7}$, and $\mathrm{PMe}_{3}, \mathbf{5 - 2 9}$, and both 5-2a and 5-2b for L $=\mathrm{PPh}_{2} \mathrm{OMe}, \mathbf{5 - 2 8}, \mathrm{PMe}(\mathrm{OEt})_{2}, \mathbf{5 - 3 0}, \mathrm{P}\left(\mathrm{OEt}_{3}\right), 5$ 5-31, $\mathrm{PPh}(\mathrm{OEt})_{2}, 5$ 5-32, have been included in the experimental section. Interestingly, all 5-2a complexes exhibit nonequivalent ${ }^{t}$ butyl groups, whereas all 5-

2b complexes have equivalent ${ }^{t}$ butyl groups. This is similar to the NMR spectra observed for 5-8, 5-7, and $\mathbf{5 - 5}$, in which nonequivalent ${ }^{t}$ butyl groups were indicative of formation of $\mathbf{5 - 1}$ a and equivalent ${ }^{t}$ butyl groups for $\mathbf{5 - 1 b}$. Additionally, the trans hydrides shifts for $\mathbf{5 - 2 b}$, when $\mathrm{L}=\mathrm{PR}_{3}$, are observed as quartets, indicating coupling by three phosphorous nuclei. In the case of $\mathrm{L}=\mathrm{N}$-type or S -type ligands, then the hydrides are observed as a triplet, indicative of coupling to only two phosphorous nuclei. The crystal structure of 5-23, previously reported, clearly shows the trans orientation of pyridine to the aryl ring of the (PCP) backbone (Figure 5.4) consistent with the NMR characterization. ${ }^{19}$ The crystal structures of 5-21 and 5-32b, which also show the trans orientation of $\mathrm{NCCH}_{3}$ and $\mathrm{PPhOEt}_{2}$ to the back bone of the PCP aryl backbone, are given in the same report.

Figure 5.4 Crystal Structure of 5-23

For 5-2a, the cis hydrides are observed as having two distinct shifts in the ${ }^{1} \mathrm{H}$ NMR spectrum. The hydride trans to the PCP backbone is observed as a doublet of quartets, coupled by three phosphorous nuclei as well as the other hydride. The hydride trans to $\mathrm{PR}_{3}$ is observed as a doublet of triplets of doublets; the hydride is coupled by the other hydride, two equivalent phosphorous nuclei and the trans $\mathrm{PR}_{3}$ group, giving a large trans $\mathrm{P}-\mathrm{H}$ coupling constant.

The additions of $\mathrm{NH}_{3}, \mathrm{PPh}_{3}$, and $\mathrm{PPh}_{2} \mathrm{Et}$ to $\mathbf{5 - 2}$ were studied via direct equilibrium, as described for the addition of $\mathrm{PR}_{3}$ type ligands to $\mathbf{5 - 1}$. The addition of $\mathrm{H}_{2}$ was studied via dehydrogenation of isopropanol to acetone. ${ }^{36,37}$ This equilibrium was not measured by direct addition of $\mathrm{H}_{2}$ gas to (PCP)IrH $\mathrm{I}_{2}$ because the exact concentration of $\mathrm{H}_{2}$ gas in solution would need to be determined, rendering it less
feasible then the dehydrogenation reaction. The $\Delta \mathrm{H}^{\circ}, \Delta \mathrm{S}^{\circ}$, and $\Delta \mathrm{G}^{\circ}$ for this equilibrium were measured as $3 \mathrm{kcal} / \mathrm{mol}, 9 \mathrm{cal} / \mathrm{mol} * \mathrm{~K}$, and $0.3 \mathrm{kcal} / \mathrm{mol}$ respectively. Subtraction of the values for the hydrogenation of acetone, ${ }^{38}$ can give the overall thermodynamic values for the direct addition of $\mathrm{H}_{2}$ to $\mathbf{5 - 2}$ to form 5-20 ${ }^{39}$ (Table 5.4) in which $\Delta \mathrm{H}^{\circ}, \Delta \mathrm{S}^{\circ}$, and $\Delta \mathrm{G}^{\circ}$ are $-13.4 \mathrm{kcal} / \mathrm{mol},-27 \mathrm{cal} / \mathrm{mol} * \mathrm{~K}$, and $-5.4 \mathrm{kcal} / \mathrm{mol}$ respectively.

Table 5.4 Determination of the Thermodynamic Values for the Addition of $\mathrm{H}_{2}$ to 5-2 via Dehydrogenation of Acetone

| Reaction | $\underset{(\mathrm{kcal} / \mathrm{mol})}{\Delta \mathbf{H}^{\circ}}$ | $\underset{(\mathrm{cal} / \mathrm{mol} * \mathrm{~K})}{\Delta \mathrm{S}^{\circ}}$ | $\begin{gathered} \Delta G^{\circ} \\ (\mathrm{kcal} / \mathrm{mol}) \text { at } 298 \mathrm{~K} \end{gathered}$ |
| :---: | :---: | :---: | :---: |
|  | 3.0 | 9 | 0.3 |
|  | -16.4 | -36 | -5.7 |
|  | -13.4 | -27 | -5.4 |

Again, a graph of $\Delta \mathrm{G}^{\circ}$ versus temperature (Figure 5.5) for the addition of $\mathrm{L}=\mathrm{NH}_{3}, \mathrm{PPh}_{3}, \mathrm{H}_{2}$, and $\mathrm{PPh}_{2} \mathrm{Et}$ to $\mathbf{5 - 2}$ gives $\Delta \mathrm{H}^{\circ}$ as the y-intercept and $\Delta \mathrm{S}^{\circ}$ as the slope of a linear regression (Table 5.5).

Figure 5.5 Graph of $\Delta \mathrm{G}^{\circ}(\mathrm{kcal} / \mathrm{mol})$ versus Temperature $(\mathrm{K})$ for the Addition of $\mathrm{L}=\mathrm{NH}_{3}$ (purple), $\mathrm{PPh}_{2} \mathrm{Et}$ (green), $\mathrm{PPh}_{3}$ (red), and $\mathrm{H}_{2}$ (blue) to $\mathbf{5 - 2}$

Table 5.5 Thermodynamic Parameters for the Addition of $\mathrm{L}=\mathrm{NH}_{3}, \mathrm{PPh}_{3}, \mathrm{H}_{2}$ and $\mathrm{PPh}_{2} \mathrm{Et}$ to 5-2

| ''L'' | $\boldsymbol{\Delta H}(\mathbf{k c a l} / \mathbf{m o l})$ | $\boldsymbol{\Delta S}(\mathbf{c a l} / \mathbf{m o l} * \mathbf{K})$ | $\Delta \mathbf{G}(\mathbf{k c a l} / \mathbf{m o l})$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{NH}_{3}$ | $-11.2(0.4)$ | $-31.2(1.4)$ | $-1.9(0.4)$ |
| $\mathrm{PPh}_{3}$ | $-21.7(0.4)$ | $-60.8(1.4)$ | $-3.5(0.4)$ |
| $\mathrm{H}_{2}$ | $-13.6(0.6)$ | $-27.6(1.7)$ | $-5.4(0.6)$ |
| $\mathrm{PPh}_{2} \mathrm{Et}$ | $-25.6(0.3)$ | $-62.5(0.9)$ | $-7.0(0.3)$ |

The most weakly binding ligand in this series is $\mathrm{NH}_{3}, \Delta \mathrm{G}^{\circ}=-1.9(0.4) \mathrm{kcal} / \mathrm{mol}$, and the most strongly binding ligand measured directly is $\mathrm{PPh}_{2} \mathrm{Et}, \Delta \mathrm{G}^{\circ}=-7.0(0.3) \mathrm{kcal} / \mathrm{mol}$. In this case, the more sterically hindered $\mathrm{PPh}_{3}\left(145^{\circ}\right)$ does bind less strongly then $\mathrm{PPh}_{2} \mathrm{Et}\left(140^{\circ}\right)$. Still, a distinct trend cannot be established between the binding energies for 5-2 and the Tolman parameters. The experimentally determined values for the addition of $\mathrm{PPh}_{3}$ and $\mathrm{H}_{2}$ to 5-2, were compared to computational values derived from the same functionals as were used for $\mathbf{5 - 1}$ (Table 5.6).

For the addition of $\mathrm{H}_{2}$ and $\mathrm{PPh}_{3}$ to 5-2, M06-L, B97D and M06-2X most closely correlate to the experimental values. Not surprisingly, all functionals predict the energy for addition of $\mathrm{H}_{2}$ much more accurately then for $\mathrm{PPh}_{3} . \mathrm{PPh}_{3}$ is much more sterically demanding then $\mathrm{H}_{2}$ and interacts with the ${ }^{t}$ butyl groups of 5-2, therefore Van der Waals forces and the correction for dispersion play a bigger role in the accuracy of the Minnesota functionals. TPSSh, TPSS, PBE overestimate both $\Delta \mathrm{H}^{\circ}$ and $\Delta \mathrm{G}^{\circ}$ for the
addition of $\mathrm{PPh}_{3}$ to $\mathbf{5 - 2}$ but are the values are very close together. B3LYP overestimates $\Delta \mathrm{H}^{\circ}$ and $\Delta \mathrm{G}^{\circ}$ the greatest of all the functionals that were examined.

The thermodynamics for the addition of more strongly binding ligands can again be determined via exchange equilibria as was done for 5-1. The $\Delta \mathrm{G}^{\circ}$ values range from -1.0 to $-20.4 \mathrm{kcal} / \mathrm{mol}$, and account for the addition of a wider range of ligands, including N-type, S-type, and $\mathrm{PR}_{3}$ (Table 5.7). The experimentally determined values were again compared to values obtained from the M06-L and PBE functionals. The equilibrium constants for all equilibria are included in the experimental section. The same trend is observed with $\mathbf{5 - 2}$ as with $\mathbf{5 - 1}$, PBE is much less successful at accurately predicting the experimental values. The only complexes that PBE predicts fairly accurately are $\mathbf{5 - 1 6}, \mathbf{5 - 2 0}$ and $\mathbf{5 - 2 1}$, which is not surprising because, as was seen for $\mathbf{5 - 5}, \mathrm{NH}_{3}, \mathrm{H}_{2}$ and $\mathrm{NCCH}_{3}$ are small organic ligands and are not affected by the Van der Waals forces as much as with the $\mathrm{PR}_{3}$ ligands.

Table 5.7 Experimental $\Delta \mathrm{G}^{\circ}$ Values $(\mathrm{kcal} / \mathrm{mol})$ for the Addition of a Series of Ligands to $\mathbf{5 - 2}$ Compared to Computational Values ( $\mathrm{kcal} / \mathrm{mol}$ ) Determined using M06-L and PBE functionals

A comparison of the experimental values and the computational results are better represented in a graph of the experimental values versus the computational values (Figure 5.6). The linear regression for values predicted by the PBE functional, in red, is higher than the experimental regression by a factor of 6.2 units, whereas the regression lines for the values predicted by M06-L, in blue, is only 0.2 units higher than the experimental values, shown by black line. In fact, the regression for M06-L lies directly on the experimental regression.

Figure 5.6 Graph of Experimental $\Delta \mathrm{G}^{\circ}$ Values versus Computational $\Delta \mathrm{G}^{\circ}$ Values for the Addition of Ligands to 5-2, [Experimental (black), PBE (red), and M06-L (blue), $\Delta \mathrm{G}(\mathrm{kcal} / \mathrm{mol})]$.

These two functionals show much better agreement for the addition of $L$ to $\mathbf{5 - 2}$ then was observed for addition of L to $\mathbf{5 - 1}$. This may be due to the difference in the steric hindrance of a chloride versus a hydride ligand. Essentially, the chloride should pose a greater challenge for the functionals to calculate as it may interact with ligands more than a hydride ligand, hence PBE does a better job of predicting energies for $\mathbf{5 - 2}$ then $\mathbf{5 - 1}$. Also, the rapid isomerization of $\mathbf{5 - 1}$ a to $\mathbf{5 - 1 b}$ for the N -type ligands may also lead to decreased accuracy for $\mathbf{5 - 1}$ versus $\mathbf{5 - 2}$. The root mean square for the addition of ligands to $\mathbf{5 - 2}$ determined using the M06-L functional is $2.3 \mathrm{kcal} / \mathrm{mol}$, meanwhile it is $11.2 \mathrm{kcal} / \mathrm{mol}$ for the values determined by the PBE functional.

### 5.2.3 Equilibrium Studies of (PCP)Ir, 5-3

Addition of L to 3-coordinate $14 \mathrm{e}^{-}$species 5-3 leads to synthesis of the four coordinate species. All complexes 5-33-5-59, in which $L=$ norbornene, 5-33, cyclooctene, 5-34, trans-2-hexene, 5-35, benzene, 5-36, aniline, 5-37, 2-picoline, 5-38, 1-hexene, 5-39, furan, 5-40, DBT, 5-41, propylene, 5-42, $\mathrm{PPh}_{2} \mathrm{Et}, \mathbf{5 - 4 3}, \mathrm{PPh}_{3}, 5-44$, thiophene, 5-45, $\mathrm{N}_{2}, \mathbf{5 - 4 6}$, pyridine, 5-47, isoquinoline, 5-48, $\mathrm{PEt}_{3}, 5-49$, $\mathrm{CH}_{3} \mathrm{CN}, \mathbf{5 - 5 0}, \mathrm{PPh}_{2} \mathrm{Me}, \mathbf{5 - 5 1}$, phenol, 5-52, ethylene, 5-53, $\mathrm{PMe}_{2} \mathrm{Ph}, \mathbf{5 - 5 4}, \mathrm{PMe}_{3}, \mathbf{5 - 5 5}, \mathrm{PPh}_{2} \mathrm{OMe}, \mathbf{5 - 5 6}$, $\mathrm{PPh}(\mathrm{OEt})_{2}, \mathbf{5 - 5 7}, \mathrm{PMe}(\mathrm{OEt})_{2}, \mathbf{5 - 5 8}$, and $\mathrm{P}\left(\mathrm{OEt}_{3}\right), \mathbf{5 - 5 9}$, have been characterized by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy, which have been included in the experimental section whereas the crystal structure of $\mathbf{5 - 5 0}$, 5-54, and 5-59 has been included following the experimental section.

As discussed in Chapter 2, species $\mathbf{5 - 3}$ has never been isolated and all attempts to do so have proven unsuccessful. It is now understood, that the equilibrium between $\mathbf{5 - 3}$ and L lies too far to the right to be directly measured (Scheme 5.6). Therefore, the binding energies of L to $\mathbf{5 - 3}$ must be determined relatively using exchange equilibria, vide infra.

Scheme 5.6 Equilibrium Exchange between 5-3 and L

An anchor point is needed to calibrate the relative thermodynamics of $\mathbf{5 - 3}$. The displacement of pyridine by $\mathrm{CH}_{3} \mathrm{CN}$ was studied with varying concentrations of both pyridine and $\mathrm{CH}_{3} \mathrm{CN}$ by Sabuj Kundu. ${ }^{19}$ Displacement of pyridine can either follow a dissociative (Scheme 5.7) or associative pathway.

Scheme 5.7 Dissociative Pathway for the Displacement Pathway of Pyridine by Acetonitrile

The results from these kinetics experiments are shown in Figure 5.7. The dots correspond to experimental data, whereas the lines correspond to fitted data using the Gepasi Software program ${ }^{41}$ Varying the concentration of $\mathrm{CH}_{3} \mathrm{CN}$ shows no change in the rate, whereas, an increase in pyridine concentration shows a decrease in reaction rate. The rate of reaction is only dependent upon loss of pyridine from the iridium center, as shown by the fit of the data, therefore this reaction follows a dissociative pathway.

Figure 5.7 Experimental and Gepasi Fit Data for the Dissociation of Pyridine from 5-3

An Eyring plot of $\ln (\mathrm{k} / \mathrm{T})$ versus $1 / \mathrm{T}$ of this data (Figure 5.8) gives $\Delta \mathrm{H}^{\dagger}=24.9$ (1) $\mathrm{kcal} / \mathrm{mol}$ and $\Delta \mathrm{S}^{\ddagger}=12.1(4) \mathrm{cal} / \mathrm{mol} * \mathrm{~K}$.

Figure 5.8 Eyring Plot for the Dissociation of Pyridine

| $\mathbf{T}(\mathbf{K})$ | $\mathbf{k}_{\mathbf{1}}\left(\mathbf{M}^{\mathbf{- 1}} \mathbf{s}^{\mathbf{- 1}}\right)$ |
| :---: | :---: |
| 303 | 0.00308203 |
| 293 | 0.00076552 |
| 288 | 0.0003519 |
| 283 | 0.0001619 |

$\Delta \mathrm{H}^{\ddagger}=24.9$ (1) $\mathrm{kcal} / \mathrm{mol}, \Delta \mathrm{S}^{\ddagger}=12.1$ (4) $\mathrm{cal} / \mathrm{mol} * \mathrm{~K}$

The $\Delta \mathrm{H}^{\ddagger}=24.9 \mathrm{kcal} / \mathrm{mol}$ is considered to be the upper limit for the $\Delta \mathrm{H}$ of $\mathbf{5 - 3}$ binding. The barrier to addition is assumed to be very small and therefore only slightly above the actual value of $\Delta \mathrm{H}$. All $\Delta \mathrm{H}$ values for other $L$ are determined relative to pyridine via equilibrium exchange experiments. We can assume that $\Delta \Delta \mathrm{S}$ will be negligible and so the $\Delta \mathrm{G}$ for addition of pyridine can be set to $0.0 \mathrm{kcal} / \mathrm{mol}$. For example, the exchange equilibrium between pyridine and $\mathrm{PEt}_{3}$ was measured from 25 to $65{ }^{\circ} \mathrm{C}$. The $\Delta \mathrm{G}^{\circ}$ versus temperature graph is shown in Figure 5.9 and the $\Delta \mathrm{H}^{\circ}, \Delta \mathrm{S}^{\circ}$ and $\Delta \mathrm{G}^{\circ}$ are shown below the graph. Therefore, $\Delta \mathrm{G}_{\text {rel }}$ for the addition of $\mathrm{PEt}_{3}$ is $-1.5 \mathrm{kcal} / \mathrm{mol}$.

| $\left.\boldsymbol{\Delta} \mathbf{H}^{\circ} \mathbf{( k c a l} / \mathbf{m o l}\right)$ | $\boldsymbol{\Delta} \mathbf{S}^{\circ}(\mathbf{c a l} / \mathbf{m o l} * \mathbf{K})$ | $\boldsymbol{\Delta} \mathbf{G}^{\circ}$ at $\mathbf{2 9 8} \mathbf{~ K}(\mathrm{kcal} / \mathrm{mol})$ |
| :---: | :---: | :---: |
| $-7.1(0.4)$ | $-18(1.3)$ | $-1.5(0.1)$ |

The $\Delta \mathrm{G}_{\text {rel }}$ values for addition of L relative to addition of pyridine to $\mathbf{5 - 3}$ are listed in Table 5.8. The equilibrium constants for all equilibria have also been included in the experimental section. The most strongly binding ligand is $\mathrm{P}(\mathrm{OEt})_{3}, \Delta \mathrm{G}_{\mathrm{rel}}=-10.9 \mathrm{kcal} / \mathrm{mol}$, and the most weakly binding ligand is norbornene, $\Delta \mathrm{G}_{\text {rel }}=-9.9 \mathrm{kcal} / \mathrm{mol}$. The experimental $\Delta \mathrm{G}_{\text {rel }}$ values were compared to computational values determined using the M06-L and PBE functionals, just as was done for 5-1 and 5-2.

Table 5.8 Relative Experimental $\Delta \mathrm{G}$ Values ( $\mathrm{kcal} / \mathrm{mol}$ ) for the Addition of Ligands to 5-3 Compared to Computational Values ( $\mathrm{kcal} / \mathrm{mol}$ ) Determined using M06-L and PBE Functionals

| $\mathrm{PMe}(\mathrm{OEt})_{2}$ | -9.8 | -13.2 | -6.0 |
| $\mathrm{P}(\mathrm{OEt})_{3}$ | -10.9 | -18.1 | -12.6 |

Interestingly, mixed results are obtained. M06-L does very well at predicting the energies for addition of the phosphines, but this functional cannot predict the addition of the phosphites well. PBE does a better job at predicting the values of $\mathbf{5 - 5 9}, \mathbf{5 - 5 8}$, and $\mathbf{5 - 5 7}$, but does not predict the values of the phosphines, i.e., $\mathbf{5 - 4 4}, \mathbf{5 - 4 9}$, or $\mathbf{5 - 5 6}$, accurately. Neither PBE or M06-L does a very good job at predicting $\mathbf{5 - 4 0}$ or 5-45, underestimating the binding energies by more than $4 \mathrm{kcal} / \mathrm{mol}$. Oddly, M06-L overestimates the binding of $\mathbf{5 - 4 6}$ by more than $7 \mathrm{kcal} / \mathrm{mol}$. Overall, M06-L predicts the binding energies much more accurately then PBE and this much easier to observe as a pictorial representation, a graph of the
experimental values versus the computational values for the addition of $L$ to $\mathbf{5 - 3}$ is shown below in Figure 5.10.

Figure 5.10 Graph of Experimental $\Delta G$ Values versus Computational $\Delta G$ Values for the Addition of Ligands to 5-3, [Experimental (black), PBE (red), and M06-L (blue), $\Delta \mathrm{G}(\mathrm{kcal} / \mathrm{mol})]$.

The values predicted by the PBE functional, in red, are much overestimated by a factor of 4.3 units, whereas the values predicted by M06-L, in blue, are only 0.2 units over the experimental values. The root mean square for values determined via M06-L is $3.6 \mathrm{kcal} / \mathrm{mol}$ while the root mean square for PBE is $6.1 \mathrm{kcal} / \mathrm{mol}$. In comparison, PBE did best in predicting the energies for $\mathbf{5 - 3}$ rather than 5-1 or 5-2.

### 5.3 Conclusions

The binding energies for a range of $\mathrm{C}, \mathrm{H}, \mathrm{O}, \mathrm{N}$, S-type and $\mathrm{PR}_{3}$ ligands were determined for addition to $\mathbf{5 - 1}, \mathbf{5 - 2}$, and $\mathbf{5 - 3}$. In the case of $\mathbf{5 - 1}$, an isomerization between $\mathbf{5 - 1 a}$ and $\mathbf{5 - 1 b}$ isomers is observed when $\mathrm{PR}_{3}$ ligands are studied but isomerization is not observed when L is an N -type ligand. The isomerization is due to bulkiness of $\mathrm{PR}_{3}$ in comparison to the chloride, so, the N -type ligands experience exchange and have much more positive entropy values in comparison to the $\mathrm{PR}_{3}$ ligands. In the case of 52, isomerization is observed for all ligands including the N-type ligands. The equilibrium between 5-3 and L lies too far to the right in order for direct measurement. Therefore, the barrier to addition $\left(\Delta \mathrm{H}^{\ddagger}=24.9\right.$
$\mathrm{kcal} / \mathrm{mol}$ ) of acetonitrile and displacement of pyridine is considered to be the anchor point and all other $\Delta \mathrm{H}$ and $\Delta \mathrm{G}$ values for the addition of L are determined relative to pyridine via equilibrium exchange experiments. Overall, the M06-L and M06 functionals have much better agreement with the experimentally determined values for the addition of ligands to all three catalyst systems most likely due to the inclusion of dispersion.

### 5.4 Experimental

### 5.4.1 General Methods

All reactions were performed under an argon atmosphere using standard Schlenck techniques or in an argon-filled glove box. Phosphines, phosphonites, phosphinites, dibenzothiophene and pyridine were purchased from Aldrich or VWR. Cyclooctene, 1-hexene, trans-2-hexene, $\mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{C}_{6} \mathrm{D}_{6}$, and $p$-xylene- $d_{10}$ were dried over $\mathrm{Na} / \mathrm{K}$ alloy and collected via vacuum transfer. Norbornene (NBE) was sublimed before use. All other substrates were degassed before entry to glovebox and used without further purification. 5-1 and 5-2 were synthesized according to literature. ${ }^{42}{ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$, and ${ }^{31} \mathrm{P}$ NMR spectra were obtained from either a 400 or 500 MHz Varian instrument. The residual peak of the deuterated solvent was used as a reference for all ${ }^{1} \mathrm{H}$ NMR spectra and an internal capillary standard of $\mathrm{PMe}_{3}$ in $p$-xylene- $d_{10}(-62.4 \mathrm{ppm})$ was used to reference ${ }^{31} \mathrm{P}$ NMR chemical shifts.

### 5.4.2 Chemical Equilibria

To a $0.5 \mathrm{~mL} p$-xylene- $\mathrm{d}_{10}$ solution, $5 \mathrm{mg} \mathbf{5 - 1}(8.04 \mu \mathrm{~mol}), 5 \mathrm{mg} \mathbf{5 - 2}(8.5 \mu \mathrm{~mol})$ or a combination of $5 \mathrm{mg} 5-2(8.5 \mu \mathrm{~mol})$ and 2.4 mg NBE $(25.5 \mu \mathrm{~mol})$ in an NMR tube, ligand was added (stock solutions in $p$ -xylene- $\mathrm{d}_{I 0}$ of each ligand were utilized and amounts have been listed in the Tables 5.9 through 5.11). The solution was sealed in an NMR tube under an argon atmosphere. The solution was monitored by ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ NMR spectroscopy at varying temperatures, ranging from -10 to $105{ }^{\circ} \mathrm{C}$. The temperature of the NMR was calibrated by ethylene glycol. ${ }^{43}$ All products were characterized by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. The characterization has been included in the experimental section, whereas crystal structures and data of select products have been included following the experimental section. The concentration of each species was determined by integration of each species, by both integration of each ${ }^{31} \mathrm{P}$ NMR shift or integration of the hydride shift for (PCP) IrHCl and (PCP) $\mathrm{IrH}_{2}$ or by the methylene protons in (PCP)Ir. The concentration
was also determined by correlation of the NMR shift of the ${ }^{31} \mathrm{P}$ or ${ }^{1} \mathrm{H}$ hydride shifts to the percentage of each species in solution for the addition of N-type ligands. The concentration was determined by correlation to the known concentration of added species or to the known concentration of an internal standard.

### 5.4.3 Exchange Equilibria

In typical equilibrium measurements, to a $0.5 \mathrm{~mL} p$-xylene- $\mathrm{d}_{10}$ solutions of $5 \mathrm{mg} \mathbf{5 - 1}(8.04 \mu \mathrm{~mol})$, $5 \mathrm{mg} \mathbf{5 - 2}(8.5 \mu \mathrm{~mol})$ or a combination of $5 \mathrm{mg} \mathbf{5 - 2}(8.5 \mu \mathrm{~mol})$ and 2.4 mg NBE $(25.5 \mu \mathrm{~mol})$ in an NMR tube, two ligands were added. The ratio of ligands has been included in Tables $5.9-5.11$ below along with reported K values. The NMR tube was sealed under an argon atmosphere. The solution was monitored by
${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy.

### 5.4.4 Dehydrogenation of Isopropanol

To a $0.5 \mathrm{~mL} p$-xylene- $\mathrm{d}_{10}$ solution of $8.93 \mu \mathrm{~L} \mathbf{5 - 2}(8.93 \mu \mathrm{~mol})$ in a J . Young NMR tube, $45 \mu \mathrm{~L} 2$ propanol ( $42.48 \mu \mathrm{~mol}$ ) was added. The solution was heated for ten days at $100{ }^{\circ} \mathrm{C}$ and equilibrium was reached. The concentrations of $\mathbf{5 - 2}$ and $\mathbf{5 - 2} \mathbf{H}_{\mathbf{2}}$ were monitored by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy, whereas the concentrations of acetone and 2-propanol were monitored by ${ }^{1} \mathrm{H}$ NMR spectroscopy only.

To a $0.5 \mathrm{ml} p$-xylene- $d_{10}$ solution of $5 \mathrm{mg} \mathrm{5-1}(8.3 \mu \mathrm{~mol})$ in a J. Young NMR tube, $8.9 \mu \mathrm{~mol}$ substrate was added and 5-4 through 5-14 were synthesized.

## (PCP) $\operatorname{IrP}(\mathbf{O E t})_{3}, \mathbf{5 - 5 9}{ }^{19}$

Complex was crystallized via slow evaporation of pentane. A crystal structure is included as Figure 5.14 and X-ray crystallography refinement and structure parameters are included in Tables 5.24 through 5.27.

The synthesis and characterization of the following complexes have been described elsewhere:
( PCP ) IrNBE, $\mathbf{5 - 3 3}{ }^{\mathbf{4 4}}$, (PCP) IrCOE, $\mathbf{5 - 3 4}{ }^{\mathbf{1 9}}$, (PCP) $\operatorname{Ir}($ trans-2-hexene $), \quad \mathbf{5 - 3 5}^{\mathbf{1 9}},(\mathrm{PCP}) \operatorname{Ir}(\mathrm{Ph})(\mathrm{H}), \mathbf{5 - 3 6}{ }^{\mathbf{4 4}}$, $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})(\mathrm{NHPh}), \quad \mathbf{5 - 3 7}{ }^{\mathbf{4 5}}, \quad(\mathrm{PCP}) \operatorname{Ir}(1-$ hexene $), \quad \mathbf{5 - 3 9}^{\mathbf{1 9}}, \quad(\mathrm{PCP}) \mathrm{IrN}_{2}, \quad \mathbf{5 - 4 6}{ }^{\mathbf{4 6}}, \quad(\mathrm{PCP}) \operatorname{IrPy}, \quad \mathbf{5 - 4 7}{ }^{\mathbf{1 9}}$, $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{PhO})(\mathrm{H}), \mathbf{5 - 5 2}{ }^{47},(\mathrm{PCP})$ IrEthylene, $\mathbf{5 - 5 3}^{19},(\mathrm{PCP}) \mathrm{IrPMe}_{3}, \mathbf{5 - 5} .{ }^{\mathbf{1 9}}$

### 5.4.8 Computational Details

DFT studies were completed by Dr. Karsten Krogh-Jespersen. All calculations used DFT methodology as implemented by Gaussian $03^{48}$ and $09^{49}$ computer programs. The LANL08 ${ }^{50}$ basis set was utilized for Ir atom, and all other atoms were treated with the 6 - $311 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis set.

Table 5.20 Crystal Data and Structure Refinement for(PCP)IrPMe ${ }_{2} \mathrm{Ph}, \mathbf{5 - 5 4}$

| Identification code | mepirh2 |
| :---: | :---: |
| Empirical formula | C32 H54 Ir P3 |
| Formula weight | 723.86 |
| Temperature | 100(2) K |
| Wavelength | 0.71073 A |
| Crystal system | Triclinic |
| Space group | P-1 |
| Unit cell dimensions | $\begin{array}{ll} \mathrm{a}=10.5794(9) \AA & \alpha=106.947(2)^{\circ} . \\ \mathrm{b}=10.9039(10) \AA & \beta=99.442(2)^{\circ} . \\ \mathrm{c}=15.5416(14) \AA & \gamma=105.492(2)^{\circ} . \end{array}$ |
| Volume | 1594.7(2) $\AA^{3}$ |
| Z | 2 |
| Density (calculated) | $1.507 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $4.356 \mathrm{~mm}^{-1}$ |
| F(000) | 736 |
| Crystal size | $0.20 \times 0.18 \times 0.02 \mathrm{~mm}^{3}$ |
| Theta range for data collection | 2.06 to $30.03^{\circ}$. |
| Index ranges | $-14<=\mathrm{h}<=14,-15<=\mathrm{k}<=15,-21<=1<=21$ |
| Reflections collected | 18172 |
| Independent reflections | $9158[\mathrm{R}(\mathrm{int})=0.0248]$ |
| Completeness to theta $=30.03^{\circ}$ | 98.2 \% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.7461 and 0.5487 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{2}$ |
| Data / restraints / parameters | 9158 / 0 / 339 |
| Goodness-of-fit on $\mathrm{F}^{2}$ | 1.002 |
| Final R indices [I>2sigma(I)] | $\mathrm{R} 1=0.0241, \mathrm{wR} 2=0.0576$ |
| R indices (all data) | $\mathrm{R} 1=0.0265, \mathrm{wR} 2=0.0588$ |
| Largest diff. peak and hole | 1.988 and -1.561 e. $\AA^{-3}$ |

Table 5.21 Atomic Coordinates $\left(\times 10^{4}\right)$ and Equivalent Isotropic Displacement Parameters $\left(\AA^{2} \times 10^{3}\right)$ for (PCP) $\operatorname{IrPMe}{ }_{2} \mathrm{Ph}, \mathbf{5 - 5 4} . \mathrm{U}(\mathrm{eq})$ is defined as one third of the trace of the orthogonalized $\mathrm{U}^{\mathrm{ij}}$ tensor.

Table 5.24 Crystal Data and Structure Refinement for (PCP) $\mathrm{IrPOEt}_{3}, \mathbf{5 - 5 9}$

| Identification code | irpoet_p21n |
| :---: | :---: |
| Empirical formula | C30 H58 Ir O3 P3 |
| Formula weight | 751.87 |
| Temperature | 100(2) K |
| Wavelength | 0.71073 A |
| Crystal system | Monoclinic |
| Space group | P2(1)/n |
| Unit cell dimensions |  |
|  | $b=17.2703(10) \AA \quad \beta=110.857(1)^{\circ}$. |
|  | $\mathrm{c}=15.8727(9) \AA \AA^{\text {a }}$ ( |
| Volume | 3312.7(3) $\AA^{3}$ |
| Z | 4 |
| Density (calculated) | $1.508 \mathrm{Mg} / \mathrm{m}^{3}$ |
| Absorption coefficient | $4.203 \mathrm{~mm}^{-1}$ |
| F(000) | 1536 |
| Crystal size | $0.55 \times 0.14 \times 0.03 \mathrm{~mm}^{3}$ |
| Theta range for data collection | 1.75 to $30.03^{\circ}$. |
| Index ranges | $-18<=\mathrm{h}<=17,-24<=\mathrm{k}<=24,-22<=1<=22$ |
| Reflections collected | 36131 |
| Independent reflections | $9540[\mathrm{R}(\mathrm{int})=0.0503]$ |
| Completeness to theta $=30.03^{\circ}$ | 98.4\% |
| Absorption correction | Semi-empirical from equivalents |
| Max. and min. transmission | 0.8843 and 0.2058 |
| Refinement method | Full-matrix least-squares on $\mathrm{F}^{2}$ |
| Data / restraints / parameters | 9540 / 513 / 377 |
| Goodness-of-fit on $\mathrm{F}^{2}$ | 1.006 |
| Final R indices [ $\mathrm{I}>2 \operatorname{sigma}(\mathrm{I})$ ] | $\mathrm{R} 1=0.0350, \mathrm{wR} 2=0.0731$ |
| R indices (all data) | $\mathrm{R} 1=0.0483, \mathrm{wR} 2=0.0779$ |
| Largest diff. peak and hole | 2.318 and -1.812 e. $\mathrm{A}^{-3}$ |

Table 5.25 Atomic Coordinates (x $10^{4}$ ) and Equivalent Isotropic Displacement Parameters ( $\AA^{2} \times 10^{3}$ ) for (PCP)IrPOEt ${ }_{3}, \mathbf{5 - 5 9}$. $\mathrm{U}(\mathrm{eq})$ is defined as one third of the trace of the orthogonalized $\mathrm{U}^{\mathrm{ij}}$ tensor.

## Chapter 6

## Dual Reactivity of Pincer Iridium Complexes towards Hydrazine

#### Abstract

The synthesis of ammonia via the Haber-Bosch process is one of the most important industrial processes in the world today. Unfortunately, it is also one of the most energy intensive processes accounting for more than $1 \%$ of the world's energy. Hydrazine $\left(\mathrm{N}_{2} \mathrm{H}_{4}\right)$ is a potential key intermediate in the conversion of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ to ammonia. We report both the dehydrogenation of hydrazine by the parent (PCP)Ir catalyst to $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ as well as the hydrogenation of hydrazine to form ammonia. (PCP)Ir complexes with hydrazine derivatives are isolated and characterized. Additionally, a computationally calculated mechanism is proposed for both pathways. Finally, the reactivity of other pincer systems towards the synthesis of ammonia is also explored.

### 6.1 Introduction

Diatomic nitrogen $\left(\mathrm{N}_{2}\right)$ persists as one the world's most plentiful molecules accounting for $78 \%$ percentage of the world's atmosphere, yet it is also considered one of the most inert molecules in chemistry. ${ }^{1,2} \mathrm{~N}_{2}$ is a poor ligand as it has little $\sigma$-donating and weak $\pi$-accepting abilities. Therefore it is no surprise that activation of the nitrogen triple bond has proved challenging. The first transition metal dinitrogen complex $\left(\left[\left(\mathrm{H}_{3} \mathrm{~N}\right)_{5} \mathrm{Ru}\left(\mathrm{N}_{2}\right)\right]^{+2}\right)$ was isolated in 1965. ${ }^{3,4}$ Since that time, the coordination chemistry of $\mathrm{N}_{2}$ has greatly expanded and dinitrogen complexes of almost every transition metal exist, becoming a promising platform for the reduction of nitrogen. ${ }^{1,5-7}$ Pincer dinitrogen species have been isolated for both the parent PCP and the more electron deficient POCOP systems as has been discussed in Chapter 2. ${ }^{8-10}$

The conversion of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ to ammonia, $\mathrm{NH}_{3}$, is an exothermic process, $-92 \mathrm{~kJ} / \mathrm{mol}(-22$ $\mathrm{kcal} / \mathrm{mol}$ ), and believed to occur through three consecutive steps (Equation 1). ${ }^{11}$

Nature has utilized an iron-molybdenum-sulfur enzyme to catalyze this reaction under ambient conditions on the order of $10^{8}$ tons per year. ${ }^{12,13}$ And although the enzymatic hydrogenation of $\mathrm{N}_{2}$ has been of great interest, the ability to mimic and understand this process is extremely limited. There are different proposed mechanisms for the synthesis of ammonia, but the generally accepted pathways involve stepwise additions of protons and electrons to reduce $\mathrm{N}_{2}$ (i.e Chatt or Schrock type mechanisms). ${ }^{14-17}$

Industrially, $\mathrm{N}_{2}$ has become a feedstock for three different processes: the Birkeland-Eyde process which generates nitric acid via electric discharge into an oxygen-nitrogen gas mixture, the Frank-Caro cyanamide process which reacts $\mathrm{N}_{2}$ with calcium carbide to produce $\mathrm{CaCN}_{2}$, and the Haber-Bosch process which generates $\mathrm{NH}_{3}$ from $\mathrm{N}_{2}$ and $\mathrm{H}_{2}{ }^{1,11}$ The Haber-Bosch process reaction utilizes an iron catalyst at high temperatures $\left(350-550{ }^{\circ} \mathrm{C}\right)$ and high pressures of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}(150-350 \mathrm{~atm})$ and consumes $1.5 \%$ of the global energy. ${ }^{18}$ This process relies on the use of $\mathrm{H}_{2}$, in the form of syngas, rather than use of proton and electron sources.

The challenge with the conversion of dinitrogen and hydrogen to ammonia lies with the high stability and inertness of $\mathrm{N}_{2} .{ }^{2}$ The $\mathrm{N}_{2}$ molecule has a very high bond energy, high ionization potential and
negative electron affinity. The first bond dissociation of the $\mathrm{N}_{2}$ triple bond requires at least $410 \mathrm{~kJ} / \mathrm{mol}$ (98 $\mathrm{kcal} / \mathrm{mol})$, whereas acetylene requires $222 \mathrm{~kJ} / \mathrm{mol}(53 \mathrm{kcal} / \mathrm{mol})$ for the analogous bond dissociation. The difference between the two molecules stems from the repulsion of the two electron pairs in the $\pi$-bond of diazene. Consequently, the 2-electron addition of $\mathrm{H}_{2}$ to acetylene to give ethylene is permitted and highly exothermic, whereas the same reaction for $\mathrm{N}_{2}$ to make $\mathrm{N}_{2} \mathrm{H}_{2}$ is forbidden and highly endothermic. Conversely, 4- and 6-electron reactions with $\mathrm{N}_{2}$ are much more favorable. Therefore any reduction of $\mathrm{N}_{2}$ should go through a hydrazine intermediate or directly to ammonia. Not only is hydrazine an intermediate in the formation of ammonia, the reverse process could potentially allow for the reduction of hydrazine to give hydrogen and nitrogen. ${ }^{19,20}$ The decomposition of hydrazine can occur via the following reactions.

$$
\begin{align*}
& 3 \mathrm{~N}_{2} \mathrm{H}_{4} \rightarrow 4 \mathrm{NH}_{3}+\mathrm{N}_{2}  \tag{2}\\
& \mathrm{~N}_{2} \mathrm{H}_{4} \rightarrow \mathrm{~N}_{2}+2 \mathrm{H}_{2}  \tag{3}\\
& \mathrm{~N}_{2} \mathrm{H}_{4} \rightarrow \mathrm{NH}_{3}+1 / 2 \mathrm{~N}_{2}+1 / 2 \mathrm{H}_{2} \tag{4}
\end{align*}
$$

Hydrazine as a hydrogen storage feedstock will generate $12.5 \%$ hydrogen by mass, in comparison to the reduction of ammonia which is the highest reported source ( $17.8 \%$ ). Other feedstocks, including boranes and borohydrides tend to give between $5.6 \%$ and $13.6 \%$ hydrogen by mass. Advantageously, hydrazine can be reduced at room temperature or slightly above, rather than $600{ }^{\circ} \mathrm{C}$ as for the decomposition of ammonia.

C-H activation has been studied extensively using pincer complexes; therefore the examination of $\mathrm{N}-\mathrm{H}$ activation by pincer iridium complexes is a natural progression given that $\mathrm{N}-\mathrm{H}$ and $\mathrm{C}-\mathrm{H}$ bonds have similar homolytic bond strengths $\left(D^{\circ}{ }_{298}=338 \mathrm{~kJ} / \mathrm{mol}, 81 \mathrm{kcal} / \mathrm{mol}^{21}\right) .{ }^{22}$ Hydroamination using pincer iridium complexes has yet to be reported, but the oxidative addition of $\mathrm{N}-\mathrm{H}$ bonds using the parent ( ${ }^{\text {tBu4 }} \mathrm{PCP}$ ) Ir (Scheme 6.1), the more electron withdrawing (POCOP)Ir complex, and other pincer motifs have been previously reported. ${ }^{23-28}$ Milstein and coworkers also reported the $\mathrm{N}-\mathrm{H}$ activation of anilines using dearomatized pincer complexes. ${ }^{29,30}$ The dehydrogenation of secondary amines to give imines, involving both $\mathrm{C}-\mathrm{H}$ and $\mathrm{N}-\mathrm{H}$ activation in which hydrogen elimination occurs across the $\mathrm{C}-\mathrm{N}$ bond rather than the C C bonds, has also been published. ${ }^{31}$

Scheme 6.1 N-H Activation of Ammonia and Aniline by ( $\left.{ }^{\text {tBu4 }} \mathrm{PCP}\right)$ Ir

The conversion of nitrogen and hydrogen to ammonia, either directly or through potential intermediates, has been investigated with a few pincer type complexes. Similar to the conversion process observed in nature, Nishibayashi and coworkers describe the conversion of dinitrogen to ammonia in the presence of cobaltocene and lutidinium triflate as the electron and proton source, respectively, with a tridentate PNP pincer type molybdenum catalyst. ${ }^{32}$ A (NNN)Fe complex has been reported for the cleavage of hydrazine utilizing proton-coupled electron transfer via transfer from the bis(pyrazole) backbone to the redox active iron center. ${ }^{33}$ Arnold and Rozenel have explored bimetallic ruthenium pincer complexes that support a series of hydrogen, nitrogen, diazene and hydrazine complexes in hopes to gain insight into nitrogenase-like activity. ${ }^{34}$

Each of these systems requires the assistance of electron and proton sources, either through an external additive or via ligand assisted transformations. The ability to use $\mathrm{H}_{2}$ directly as in the Haber Bosch Process is much more enticing as it is more atom-economical. There have been some previous studies with non pincer type complexes. For example, Chirik has investigated the hydrogenation of nitrogen extensively using early transition metals. ${ }^{6,35-42}$ Fryzuk has also published the stoichiometric addition of $\mathrm{H}_{2}$ to a side-on bound zirconium complex. ${ }^{43}$ Nishibayshi published the protonation of tungsten dinitrogen complexes assisted via a hydrogenated ruthenium complex. ${ }^{44}$ Only one report using a pincer complex has reported the direct use of $\mathrm{H}_{2}$ via hydrogenolysis of a ruthenium nitride complex, using a PNPtype ligand, to produce ammonia. ${ }^{45}$

An extensive computational study was conducted by Leitner, et. al to discuss the applications of pincer complexes for the synthesis of ammonia from $\mathrm{N}_{2}$ and $\mathrm{H}_{2} .{ }^{46}$ Ruthenium, iron, and osmium complexes with a variety of ligand backbones containing N, O and S donor atoms were investigated. The authors discovered a (POP)Ru catalyst is the most feasible for the catalytic conversion of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ to ammonia. However, generation of a dihydride dinitrogen complex, in which the dinitrogen ligand is sideon bound rather than end-on, is necessary for the catalytic cycle which may impede experimental applications due to rarity. The Hartwig group has explored the oxidative addition of hydrazine derivatives to iridium(I) complexes. ${ }^{47}$ Initial addition leads to $\mathrm{N}-\mathrm{H}$ bond activation rather than $\mathrm{C}-\mathrm{H}$ activation of the R groups (Scheme 6.2).

Scheme 6.2 Addition of Hydrazine Derivatives to (PCP)IrPhH

Specifically, reactions with methylphenylhydrazine $\left(\mathrm{MePhNNH}_{2}\right)$ and dimethylhydrazine, $\left(\mathrm{Me}_{2} \mathrm{NNH}_{2}\right)$ proceed through both double N - H activation and/or $\alpha$-methyl C - H activation followed by subsequent N-N bond cleavage (Scheme 6.3). Two mechanistic pathways are proposed for the formation of these products. Double N-H activations leads to the evolution of $\mathrm{H}_{2}$ and a diazene adduct, whereas initial $\mathrm{C}-\mathrm{H}$ activation followed $\mathrm{N}-\mathrm{N}$ bond cleavage leads to formation of ammonia and the isocyanide complex. The $\mathrm{N}-\mathrm{N}$ bond is weaker in hydrazine than within substituted hydrazines, therefore, it potentially has a higher reactivity for the formation of ammonia.

Scheme 6.3 Addition of $\mathrm{MePhNNH}_{2}$ and $\mathrm{Me}_{2} \mathrm{NNH}_{2}$ to (PCP)Ir Fragment

This chapter will report both the dehydrogenation of hydrazine by the parent (PCP)Ir catalyst to $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ as well as the hydrogenation of hydrazine to form ammonia. A series of (PCP)Ir hydrazine complexes are isolated and characterized. Thermodynamic and kinetics experiments were used to support a computationally calculated mechanism. Interestingly, hydrazine acts as both a hydrogen donor and acceptor, and no external proton source or reductant is needed to promote this reaction.

### 6.2 Results and Discussion

### 6.2.1 Synthesis of Hydrazine Complexes

At room temperature, hydrazine $\left(1 \mathrm{M}\right.$ in $\mathrm{THF}^{48,49}$ ) is reacted with $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{Ph})(\mathrm{H}){ }^{50}$ to initially generate (PCP) $\mathrm{IrN}_{2} \mathrm{H}_{4}(\mathbf{6 - 1}$, Scheme 6.4) which is qualitatively observable by a red to orange color change. The NMR spectra of $\mathbf{6 - 1}$ show a major peak at 68.9 ppm in the ${ }^{31} \mathrm{P}$ NMR spectrum and no observable hydride in the proton NMR. The hydrazine protons for the iridium bound nitrogen $(\beta-\mathrm{N})$ protons appear as a broad singlet at 4.8 ppm and the protons attached to the nitrogen bound to the iridium center $(\alpha-\mathrm{N})$ triplet at 3.2 ppm in the proton spectrum. Presumably, the broad nature of the signal for $\beta-\mathrm{N}$ protons is due to the rotation around the $\mathrm{N}-\mathrm{N}$ bond on the NMR timescale or due to the ${ }^{14} \mathrm{~N}$ quadrapole moment. Complex 6-1 is not stable at room temperature and within a few minutes, the transformation from $\mathbf{6 - 1}$ to $(\mathrm{PCP}) \mathrm{IrH}_{2} \mathrm{~N}_{2} \mathrm{H}_{4}(6-$ $\mathbf{2 a}$ ) is observed by NMR spectroscopy. The ${ }^{31} \mathrm{P}$ NMR spectrum of $\mathbf{6 - 2 a}$ shows a major peak at 66.4 ppm and a hydride signal appears at -8.8 ppm as a triplet in the ${ }^{1} \mathrm{H}$ NMR spectrum, indicative of a six-coordinate $\operatorname{Ir}(\mathrm{I})$ species (see Chapter 5 for other examples of six coordinate species). A coupled ${ }^{31} \mathrm{P}$ NMR spectrum of 6-2a gives a triplet, indicating coupling to two hydrides. The signals for the protons bound $\beta-N$ appear as a broad singlet at 3.8 ppm (also due to rotation around $\mathrm{N}-\mathrm{N}$ bond on the NMR timescale or the ${ }^{14} \mathrm{~N}$
quadrapole moment), whereas the signals of the protons attached to the $\alpha-\mathrm{N}$ appear as a triplet at 2.95 ppm . Reacting (PCP) $\mathrm{IrH}_{2}$ with hydrazine at room temperature, instead of $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{Ph})(\mathrm{H})$, gives species 6-2a immediately and $\mathbf{6 - 1}$ is not observed.

Scheme 6.4 Addition of Hydrazine and Phenylhydrazine to (PCP)Ir Complexes to Synthesize (PCP)Ir Hydrazine Complexes 6-1 through 6-2d

Complex 6-2a was crystallized from a solution of pentane and excess hydrazine solution (1 M in THF). The crystal structure contains hydrazine bound in an end-on binding mode. The $\beta$ - N in the hydrazine ligand shows slight disorder of $15 \%$ as the hydrazine ligand can swing either to the left or right (Hydrogen atoms for the PCP ligand have been omitted for clarity, Figure 6.1). Interestingly, the two isomers have different $\mathrm{N}-\mathrm{N}$ bond lengths. The major isomer has a $\mathrm{N}-\mathrm{N}$ bond length of $1.45 \AA$ whereas the minor isomer has an $\mathrm{N}-\mathrm{N}$ bond length of $1.50 \AA$, which is slightly elongated from the $\mathrm{N}-\mathrm{N}$ bond length of free hydrazine $(1.46 \AA) .{ }^{51}$ The $\mathrm{N}-\mathrm{N}$ bond lengths for the (PCP) $\mathrm{IrN}_{2}$ monomer and dimer, reported as 1.107 and 1.134-1.176 $\AA$, respectively, have also been lengthened in comparison to the $\mathrm{N}-\mathrm{N}$ bond length of free nitrogen $\left(1.095 \AA\right.$ ). ${ }^{2,8,9}$

Figure 6.1 Crystal Structure of (PCP) IrH $_{2} \mathrm{~N}_{2} \mathrm{H}_{4}$, 6-2a

Low temperature NMR experiments were conducted in mesitylene- $d_{12}$ to monitor the formation of 6-1 after the addition of hydrazine to $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{Ph})(\mathrm{H})$. At $-30^{\circ} \mathrm{C}$, there is one major peak at 45.4 ppm in the
${ }^{31} \mathrm{P}$ NMR spectrum and a hydride signal appearing as a triplet at -21 ppm , integrating to one hydrogen in relation to the butyl protons in the ${ }^{1} \mathrm{H}$ NMR spectrum, most likely corresponding to the hydrazine adduct of $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{Ph})(\mathrm{H})(\mathbf{6 - 1 b})$. As the temperature is raised from $-30{ }^{\circ} \mathrm{C}$ to $0{ }^{\circ} \mathrm{C}$, the ${ }^{31} \mathrm{P}$ NMR shift for 6-1 emerges while the signals for $\mathbf{6 - 1 b}$ decrease. Due to the transient nature of $\mathbf{6 - 1 b}$, further spectroscopic characterization was not achieved, but presumably loss of benzene from the reaction mixture leads to observance of 6-1. Again, 6-1 is not stable at room temperature and 6-2a is observed as the major species in solution upon warming from $0{ }^{\circ} \mathrm{C}$ to room temperature.

Scheme 6.5 Low Temperature Reactions for the Addition of Hydrazine to (PCP)Ir

Other hydrazine complexes can be generated using similar methods. Upon reaction of (PCP)IrHCl with hydrazine at room temperature, a yellow partially soluble product is formed which was subsequently characterized as the hydrazine adduct (PCP) $\operatorname{IrHClN}_{2} \mathrm{H}_{4}(\mathbf{6 - 2 b}$, Scheme 6.4). The NMR spectra of $\mathbf{6 - 2 b}$ shows a major peak at 50.3 ppm in the ${ }^{31} \mathrm{P}$ NMR spectrum and a hydride at -21.2 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum. The hydrazine protons are observed as broad singlets at 4.2 ppm and 4.1 ppm in the proton spectrum. Presumably, the low solubility of the complex in arene solvents does not allow for complete resolution of any coupling as was observed for $\mathbf{6 - 1}$ or $\mathbf{6 - 2 a} .{ }^{52}$ Addition of phenylhydrazine to (PCP) $\mathrm{IrH}_{2}$ leads to six coordinate ( PCP ) $\mathrm{IrH}_{2}\left(\mathrm{NH}_{2} \mathrm{NHPh}\right)$ and reaction with (PCP) IrHCl leads to (PCP) $\operatorname{IrHCl}\left(\mathrm{NH}_{2} \mathrm{NHPh}\right)$ at room temperature (6-2c and 6-2d, respectively). The NMR spectra show major peaks at 66.6 and 47.8 ppm in the ${ }^{31} \mathrm{P}$ NMR spectrum and hydrides at -8.5 and -22 ppm in the ${ }^{1} \mathrm{H}$ NMR, respectively. The hydrazine protons are observed at $\sim 5.4 \mathrm{ppm}$ for the $\beta$-nitrogen proton and $\sim 5.0 \mathrm{ppm}$ for the two $\alpha$-nitrogen protons in the ${ }^{1} \mathrm{H}$ NMR spectrum. As in the reaction with (PCP) IrHCl and hydrazine, 6$\mathbf{2 d}$ is only sparingly soluble in arene solvents.

### 6.2.2 Dehydrogenation of Hydrazine

Placing a solution of 6-2a under extended vacuum and slightly elevated temperatures $\left(50{ }^{\circ} \mathrm{C}\right)$ results in the observation of $(\mathrm{PCP}) \operatorname{IrN}_{2}$ and (PCP) $\operatorname{IrH}_{2}$ in a 1 to 3 ratio as confirmed by NMR spectroscopy (Scheme 6.6). ${ }^{8}$ Depending upon the concentrations of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ in solution, (PCP) $\operatorname{Ir} \mathrm{N}_{2}$ dimer and (PCP) $\mathrm{IrH}_{4}$ have also been observed by NMR spectroscopy. Presumably, successive N-H activation of hydrazine generates free hydrogen and nitrogen which coordinate to the naked $14 \mathrm{e}^{-}(\mathrm{PCP}) \mathrm{Ir}$ species in accordance with decomposition Equation 3. Alternatively, dehydrogenation to give diazene and $\mathrm{H}_{2}$ followed by disproportionation to produce $\mathrm{N}_{2}$ could also be a possibility.

Scheme 6.6 Formation of (PCP) $\mathrm{IrN}_{2}$ and (PCP) $\mathrm{IrH}_{2}$ from (PCP) $\mathrm{IrH}_{2} \mathrm{~N}_{2} \mathrm{H}_{4}$

This is the first example of an unassisted dehydrogenation of hydrazine using a transition metal complex. The base-induced dehydrogenation of ruthenium hydrazine complexes has been previously reported. ${ }^{53}$ The base initiates deprotonation followed by release of a pendant phosphine arm allowing for disproportionation and, finally, rearrangement of the diazene intermediate generates hydrogen and nitrogen. There is no indication of any transitional species or pendant phosphine arms in the above reaction. The dehydrogenation or more aptly phrased decomposition of hydrazine has been extensively studied as use as a hydrogen storage material but mostly with heterogeneous type catalysts. ${ }^{19,20}$

### 6.2.3 Synthesis of Ammonia

If (PCP) $\mathrm{IrH}_{2}$ is heated to $100^{\circ} \mathrm{C}$ for 1 hour in the presence of 5 equivalents hydrazine, the solution changes from yellow to dark green yielding (PCP) $\mathrm{IrH}_{2} \mathrm{NH}_{3}(\mathbf{6 - 3})$ either (PCP) $\mathrm{IrH}_{4}$ or $(\mathrm{PCP}) \mathrm{IrH}_{2}$ and free ammonia which are observable by NMR spectroscopy (Scheme 6.7). Free nitrogen is not observable by NMR, but is presumably also formed as a product following decomposition Equation 6. The ${ }^{31} \mathrm{P}$ NMR spectrum of $\mathbf{6 - 3}$ shows a signal at 67.4 ppm and a hydride signal is present in the ${ }^{1} \mathrm{H}$ NMR spectrum for two protons at -8.7 ppm , observed as a triplet, which are indicative of a six-coordinate species. The amine protons are observed as a broad signal at approximately 2.2 ppm . ( PCP ) $\mathrm{IrH}_{2}$ was reacted with 10 eq. ammonia, independently, successfully generating $\mathbf{6 - 3}$ as the sole iridium product. Free ammonia is observed in solution as a broad triplet at 0 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum. The observed splitting is due to ${ }^{14} \mathrm{~N}-{ }^{1} \mathrm{H}$ coupling ( $J_{\text {obs }}=41.2 \mathrm{~Hz}$ ). Other literature sources have cited a triplet with a coupling constant ranging from 38.1 to $43.5 \mathrm{~Hz} .^{45,54}$

Scheme 6.7 Formation of Ammonia from (PCP) $\mathrm{IrH}_{2} \mathrm{~N}_{2} \mathrm{H}_{4}$

### 6.2.4 Preliminary Catalytic Screening

When 0.1 M hydrazine is heated in the presence of a $0.02 \mathrm{M}(\mathrm{PCP}) \mathrm{IrH}_{2}$ catalyst solution, no decomposition of catalyst was detected and, within 30 minutes the reaction reached $98 \%$ completion
generating ammonia in situ (Table 1). The concentration of $\mathrm{NH}_{3}$ was determined by the comparison against a $14 \mathrm{mM} \mathrm{PMe}_{3}$ capillary insert. When a hydrazine solution is heated in a $100{ }^{\circ} \mathrm{C}$ oil bath for 72 hours without the presence of any catalyst, less then $\sim 5 \%$ conversion to ammonia was observed, supporting an iridium-catalyzed pathway rather than thermal decomposition. It is also important to note no external reductants or proton sources were added to the reaction solution. Previously, transition metal catalyzed transformations of hydrazine to ammonia using a necessary reductant and proton source have been reported. ${ }^{55,56}$ Varying the concentration of the catalyst from 20 mM to 5 mM increases the reaction time from 30 minutes to 2 hours, and a similar yield is achieved. Increasing the concentration of hydrazine to 0.4 M takes longer for completion and $87 \%$ yield is achieved after 24 hours. When the reaction is conducted under a hydrogen atmosphere rather than an argon atmosphere, less than $60 \%$ completion is observed after 65 hours. Presumably, hydrogen inhibits the catalyst through formation of (PCP) $\mathrm{IrH}_{4}$ at low concentrations of hydrazine or during the catalytic cycle.

It has been noted that replacing the ${ }^{t}$ butyl groups attached to the phosphorous arms with isopropyl groups leads to less steric bulk surrounding the metal center, thus generating ( $\left.{ }^{i \mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2} .{ }^{57}$ Addition of hydrazine to ( $\left.{ }^{(\mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2}$ yields $\left({ }^{i \mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2}\left(\mathrm{~N}_{2} \mathrm{H}_{4}\right)\left(6-4\right.$, Scheme 6.8). The ${ }^{31} \mathrm{P}$ NMR spectrum of 6-4 shows a major peak at 53.8 ppm and a hydride signal appears at -9.3 ppm as a triplet in the ${ }^{1} \mathrm{H}$ NMR spectrum. The signals for the protons bound to the $\alpha-\mathrm{N}$ appear as a broad singlet at 2.99 ppm , whereas the signals of the protons attached to the $\beta-\mathrm{N}$ appear as a triplet at 3.7 ppm . If $\mathbf{6 - 4}$ is heated to $100{ }^{\circ} \mathrm{C}$ under similar catalytic conditions only $34 \%$ ammonia yield is produced after 3.5 hours. This catalyst is much less effective than the parent $\left({ }^{t B u 4} \mathrm{PCP}\right)$ catalyst and possible reactivity explanations will be discussed vide infra.

Scheme 6.8 Addition of Hydrazine to $\left({ }^{i \mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2}$ to yield $\left({ }^{(\mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2}\left(\mathrm{~N}_{2} \mathrm{H}_{4}\right)$, 6-4

Replacing the methylene linkers in the ligand backbone with oxygen atoms generates the more electron deficient POCOP ligand. ${ }^{58}$ Utilizing the (POCOP) $\mathrm{IrH}_{2}$ catalyst for the decomposition of hydrazine yields similar results as the parent $\left({ }^{t \mathrm{Bu} 4} \mathrm{PCP}\right)$ catalyst. When 0.1 M hydrazine is heated in the presence of a
0.02 M solution of (POCOP) $\mathrm{IrH}_{2}$ catalyst, the reaction reaches $95 \%$ completion within 30 minutes. Most likely, the electronic difference between methylene and oxygen linkers does not impact this reaction. Unfortunately, no catalytic species were isolated for the (POCOP)Ir catalyzed reaction.

Table 6.1 Ammonia Production for the Catalytic Reduction of Hydrazine with Varied Catalytic Conditions

| Catalyst | [Catalyst] M | [Hydrazine] M | Time | $\left[\mathrm{NH}_{3}\right] \mathrm{M}$ | \% yield | TON (final time) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0.020 | 0.10 | 30 min | 0.10 | 99 | 5 (30 min) |

### 6.2.5 Thermodynamic Studies

As described in Chapter 5, the equilibrium constant $\left(\mathrm{K}_{\mathrm{eq}}\right)$ between $(\mathrm{PCP}) \mathrm{IrH}_{2}$ and $\mathbf{6 - 2 a}$ or $\mathbf{6 - 3}$ can be measured by changing the temperature of the reaction mixture thereby shifting the equilibrium position. Since no intermediates are formed during this process, the binding energy can be directly correlated to the energy of addition for each ligand. The concentration of each species can be determined by integration of either the ${ }^{31} \mathrm{P}$ NMR signals of each species or by the hydride signals in the ${ }^{1} \mathrm{H}$ NMR spectrum. These concentrations are then used to determine the $\mathrm{K}_{\mathrm{eq}}$. Separate equilibrium studies were conducted allowing for the measurement of binding energy for hydrazine and ammonia to (PCP) $\mathrm{IrH}_{2}$. The equilibrium between the five coordinate $(\mathrm{PCP}) \mathrm{IrH}_{2}$ with free ammonia and six coordinate $\mathbf{6 - 3}$ was monitored by NMR
spectroscopy from $25-65^{\circ} \mathrm{C}$ (Scheme 6.9), giving an equilibrium constant for the addition as $20 \mathrm{M}^{-1}$ (Table 6.2). The enthalpy $(\Delta \mathrm{H})$, entropy $(\Delta \mathrm{S})$, and free energy ( $\Delta \mathrm{G}$ ) values were determined as -11.2 (0.4) $\mathrm{kcal} / \mathrm{mol},-44.9(1.1) \mathrm{cal} / \mathrm{mol}^{*} \mathrm{~K}$, and $2.1(0.3) \mathrm{kcal} / \mathrm{mol}$ respectively. Based on these values, $\mathrm{NH}_{3}$ binds relatively weakly and can be easily eliminated from the $(\mathrm{PCP}) \mathrm{IrH}_{2}$ catalyst at room temperature and under reaction conditions the equilibrium will be even more favorable.

Scheme 6.9 Equilibrium Between (PCP) $\mathrm{IrH}_{2}$ and $\mathrm{NH}_{3}$

The direct measurement of the binding energy of hydrazine to $(\mathrm{PCP}) \mathrm{IrH}_{2}$ is inaccessible. Hence a competition experiment was conducted between hydrazine and $\mathrm{PEt}_{3}$ using a similar method as the competition experiments detailed in Chapter 5. $\mathrm{PEt}_{3}$ binds more strongly than hydrazine by $1.1 \mathrm{kcal} / \mathrm{mol}$ and since $\mathrm{PEt}_{3}$ binds to $(\mathrm{PCP}) \mathrm{IrH}_{2}$ with a free energy of $-11.0 \mathrm{kcal} / \mathrm{mol}$, the addition of hydrazine has a free energy of $-9.9 \mathrm{kcal} / \mathrm{mol}$ relative to $\mathrm{NH}_{3}$. Hydrazine can be converted to ammonia and subsequently released, which is promoted by the weak binding energy at high concentrations of hydrazine. As discussed earlier, both free ammonia and hydrogen, in the form of $(\mathrm{PCP}) \mathrm{IrH}_{4}$, are observed by NMR spectroscopy as the reaction nears completion. Also, performing the reaction under a hydrogen atmosphere significantly impacts the reaction yield and time; $60 \%$ yield in 65 hours as compared to $98 \%$ in 30 minutes. These observations indicate there is competitive binding between hydrogen, to form (PCP) $\mathrm{IrH}_{4}$, and ammonia, to form 6-3, as the hydrazine becomes consumed. The formation of the tetrahydride complex is favorable by $5.4 \mathrm{kcal} / \mathrm{mol}$ in comparison to hydrazine and ammonia. As nitrogen is also synthesized during this reaction, experiments were conducted to determine the possibility of nitrogen binding to $(\mathrm{PCP}) \mathrm{IrH}_{2}$. Addition of a $1: 1$ nitrogen: hydrogen atmosphere to $(\mathrm{PCP}) \operatorname{IrH}_{2}$ leads to $(\mathrm{PCP}) \operatorname{IrH}_{4}$ and $(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{N}_{2}\right)$ monomer. Over time, the $(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{N}_{2}\right)$ monomer loses dinitrogen and $(\mathrm{PCP}) \operatorname{IrH}_{4}$ is the only observable species in solution. Previously, the addition of hydrogen to a three coordinate aliphatic pincer rhodium complex was calculated as $1.24 \mathrm{kcal} / \mathrm{mol}$ more favorable then addition of dinitrogen. ${ }^{59}$ It can be presumed
that hydrogen addition to $(\mathrm{PCP}) \mathrm{IrH}_{2}$ is even more preferred due to the stabilizing nature of the four hydrogen ligands.

Table 6.2 Equilibrium Constants $\left(\mathrm{K}, \mathrm{M}^{-1}\right)$ and Free Energy Values ( $\Delta \mathrm{G}, \mathrm{kcal} / \mathrm{mol}$ ) for the Addition of $\mathrm{NH}_{3}$, $\mathrm{H}_{2}$, Hydrazine, and $\mathrm{PEt}_{3}$ to (PCP) $\mathrm{IrH}_{2}$ at 298 K

| Ligands | $\mathbf{K}\left(\mathbf{M}^{\mathbf{- 1}}\right)$ | $\boldsymbol{\Delta G}(\mathbf{k c a l} / \mathbf{m o l})$ |
| :---: | :---: | :---: |
| $\mathrm{NH}_{3}$ | $23(4)$ | $-1.9(0.4)$ |
| $\mathrm{H}_{2}$ | 8437 | $-5.4(0.6)$ |
| Hydrazine | 6.2 | -9.9 |
| $\mathrm{PEt}_{3}$ |  | -11.0 |

Overall, the thermodynamics for the addition of ligands to (PCP) $\mathrm{IrH}_{2}$ support a catalytic mechanism in which hydrazine can be converted to ammonia and its subsequent release is promoted by the weak binding energy.

### 6.2.6 Reactivity of Other Pincer Catalysts

As the catalytic reactions of ( $\left.{ }^{i \mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2}$ and (POCOP) $\mathrm{IrH}_{2}$ have already been discussed, other pincer catalysts were tested to determine their feasibility. All reactions were conducted at $100{ }^{\circ} \mathrm{C}$. The catalyst concentrations, concentrations of hydrazine and ammonia, reaction time, percent yield, and turnover numbers have been reported in Table 6.3. Again, the concentration of $\mathrm{NH}_{3}$ was determined by the comparison against a $14 \mathrm{mM} \mathrm{PMe}_{3}$ capillary insert. Hemilabile pincer complexes have interesting reactivity differences in comparison to the parent PCP complexes. ${ }^{60,61}$ The recently synthesized (NCOP)IrHCl complex was reacted with hydrazine under basic conditions and, within 72 hours, $78 \% \mathrm{NH}_{3}$ yield was observed. Starting from the (NCOP)Ir(ethylene) complex does shorten the time frame from 72 hours to 24 hours and the yield improves to $97 \%$. Previously, it has been shown that pyridine stabilizes the NCOP catalyst. ${ }^{62}$ In the presence of pyridine, $17 \%$ yield of ammonia was observed after one hour. However, no catalytic species have been identified due to poor resolution of NMR signals. Asymmetrical catalysts have also been synthesized in which both a methylene and an oxygen linker have been used to give a PCOP type backbone. ${ }^{63}$ When $\left({ }^{i \mathrm{Pr} 4} \mathrm{PCOP}\right)$ Ir is reacted with hydrazine, 24 hours of heating is required to give ammonia in $52 \%$ yield. ${ }^{64}$ The ( $\left.{ }^{\text {iPr4 }} \mathrm{PCOP}\right)$ Ir catalyst seems to have reactivity similar to $\left({ }^{i \mathrm{Pr} 4} \mathrm{PCP}\right)$ Ir, presumably due to the steric environment created by the isopropyl groups and not the electronic differences
between the oxygen and methylene linkers. Overall, the parent $\left({ }^{(b 44} \mathrm{PCP}\right) \mathrm{IrH}_{2}$ catalyst is the most active and stable under these reaction conditions.

Table 6.3 Catalytic Conversion of Ammonia Using Various Pincer Complexes

| Catalyst | [Hydrazine] M | Time | $\underline{\text { Temp ( }{ }^{\circ} \mathrm{C} \text { ) }}$ | $\left[\mathrm{NH}_{3}\right] \mathrm{M}$ | \% yield |
| :---: | :---: | :---: | :---: | :---: | :---: |

### 6.2.7 Kinetic Results

The conversion of hydrazine to ammonia was studied using varying concentrations of ( PCP ) $\mathrm{IrH}_{2}$ as the catalyst. The reaction was conducted at $85^{\circ} \mathrm{C}$ for these studies to slow down the reaction and allow for easy monitoring over time. The production of ammonia and consumption of hydrazine was monitored by ${ }^{1} \mathrm{H}$ NMR spectroscopy. The concentration data for conversion of hydrazine at $85{ }^{\circ} \mathrm{C}$ in the presence of 20 mM and $10 \mathrm{mM}(\mathrm{PCP}) \mathrm{IrH}_{2}$ solutions are listed in Tables 6.4 and 6.5, respectively. The concentration of $\mathrm{N}_{2}$ was calculated via product balance based on the observed concentrations of free $\mathrm{NH}_{3}$ and $\mathrm{N}_{2} \mathrm{H}_{4}$ measured during the reaction. ${ }^{65}$ The ratio of $\mathrm{NH}_{3}$ produced versus the concentration of hydrazine consumed within
the reaction is approximately $0.99: 1$ for 20 mM catalyst and $0.93: 1$ for 10 mM catalyst. The ratios for the production of $\mathrm{N}_{2}$ versus hydrazine and ammonia are calculated as $0.5: 1$ and $\sim 0.54: 1$ for 20 mM and 10 mM catalyst, respectively. Therefore, the $\mathrm{N}-\mathrm{N}$ bond cleavage of hydrazine achieved mass balance within experimental error as proposed in Equation 4.

At 90 minutes, using 10 mM catalyst, $17 \mathrm{mM} \mathrm{NH}_{3}$ is produced; doubling the concentration of catalyst to 20 mM yields approximately double the concentration of $\mathrm{NH}_{3}, 33 \mathrm{mM}$ at this same time point. This trend continues throughout the reaction, indicating that it most likely exhibits first order dependence of catalyst. Graphing these sets of concentration data versus time gives a linear regression. The shape of the kinetic curve conforms to a zero-order regression with respect to concentration of hydrazine as well.

Figure 6.2 Conversion of Hydrazine to Ammonia Conversion at $85^{\circ} \mathrm{C}$ Catalyzed with (PCP) $\mathrm{IrH}_{2}$
$\left(\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ}=20 \mathrm{mM}\right)$ and its Representation by a Linear Regression

When the reaction is carried out at a lower $\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ}$ of 10 mM , plotting the experimental data showed that the rate of the reaction follows the proposed kinetic scheme only to conversion of $\sim 50 \%$ and then gradually decreases (Figure 6.3). One possible explanation is gradual "self-poisoning" of the catalyst, through inhibition of ammonia and free hydrogen to form $(\mathrm{PCP}) \mathrm{IrH}_{4}$ and $\mathbf{6 - 3}$ at the end of the reaction. Earlier it was described that increasing the concentration of hydrazine to 0.4 M also slows down the reaction to 24 hours. Perhaps, the higher concentration of hydrazine allows for the production of a higher concentration of hydrogen and, since competitive binding between hydrogen and ammonia exists based on the thermodynamic reactions, it can be assumed all of these factors lead to "self-poisoning" of the catalyst and longer reaction times. Further studies are being conducted to confirm this explanation. Perhaps another explanation is that the reaction under hydrogen atmosphere is occurring via a different mechanism and therefore would not follow the kinetic scheme of this reaction. Currently, it can be concluded that the ideal reaction conditions are 20 mM catalyst and 0.1 M hydrazine.

Figure 6.3 Conversion of Hydrazine to Ammonia Conversion at $85^{\circ} \mathrm{C}$ Catalyzed with (PCP) $\mathrm{IrH}_{2}$ $\left(\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ}=10 \mathrm{mM}\right)$ and its Representation by a Linear Regression

From calculated ratios, the experimental trends depicted by the regression curve, a first order rate law expression can be derived.

$$
\begin{equation*}
\left.d\left[\mathrm{NH}_{3}\right] / d \mathrm{t}=-d\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right] / d \mathrm{t}=k_{l}\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right)\right] \tag{5}
\end{equation*}
$$

The only two experimentally observed iridium complexes in the reaction are 6-2a and 6-3 (near completion). Any and all other iridium complexes are intermediates present in very small amounts and not observable by NMR spectroscopy. This experimental observation provides the basis for using the steady state approximation in kinetic analysis. Based on experimental observations, thermodynamic data, and kinetic data, a series of chemical equations can be proposed for a kinetic mechanism.

$$
\begin{equation*}
(\mathrm{PCP}) \mathrm{IrH}_{2}+\mathrm{N}_{2} \mathrm{H}_{4} \rightarrow(\mathrm{PCP}) \operatorname{IrH}_{2}\left(\mathrm{~N}_{2} \mathrm{H}_{4}\right) \tag{6}
\end{equation*}
$$

$(\mathrm{PCP}) \operatorname{IrH}_{2}\left(\mathrm{~N}_{2} \mathrm{H}_{4}\right)-\left(k_{1}\right) \rightarrow(\mathrm{PCP}) \mathrm{IrH}_{2}(\mathrm{NH})+\mathrm{NH}_{3}$
$(\mathrm{PCP}) \operatorname{IrH}_{2}(\mathrm{NH})+\mathrm{N}_{2} \mathrm{H}_{4}-\left(k_{2}\right) \rightarrow(\mathrm{PCP}) \mathrm{IrN}_{2} \mathrm{H}_{4}+\mathrm{NH}_{3}$
$(\mathrm{PCP}) \operatorname{IrN}_{2} \mathrm{H}_{4}-\left(k_{3}\right) \rightarrow(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\left(\mathrm{N}_{2}\right)+\mathrm{H}_{2}$

$$
(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\left(\mathrm{N}_{2}\right)+\mathrm{N}_{2} \mathrm{H}_{4} \quad-\left(k_{4}\right) \rightarrow \quad(\mathrm{PCP}) \operatorname{IrH}_{2}\left(\mathrm{~N}_{2} \mathrm{H}_{4}\right)+\mathrm{N}_{2}
$$

Equation 8 proceeds rapidly at room temperature as has been observed experimentally. It is practically irreversible as deemed by the thermodynamic experiments, therefore $[\mathbf{6}-2 \mathbf{a}]^{\circ} \approx\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ}$. After the transformation of hydrazine to ammonia is complete, the combined consumption of $\mathrm{N}_{2} \mathrm{H}_{4}$ in Equation 6 should include the loss of initial 6-2a $(10$ or 20 mM$)$ and the remaining free $\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]^{\circ}=100-[6-$ $\mathbf{2 a}]^{\circ}=100-\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ} \mathrm{mM}$. Decomposition of $\mathbf{6 - 2} \mathbf{a}$ with expulsion of an $\mathrm{NH}_{3}$ molecule leads to highly reactive catalytic intermediate, $(\mathrm{PCP}) \mathrm{IrH}_{2} \mathrm{NH}$ (Equation 7). This step is presumably the rate limiting step with the rate constant of $k_{1}$. Rapid transfer of protons again leads to loss of ammonia which can be released upon addition of $\mathrm{N}_{2} \mathrm{H}_{4}$ leading to experimentally observed complex 6-1 (Equation 8). Dehydrogenation of the hydrazine ligand, leads to $(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\left(\mathrm{N}_{2}\right)$ (Equation 9). Ligand exchange in $(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\left(\mathrm{N}_{2}\right)$ leads to the expulsion of $\mathrm{N}_{2}$ and regeneration of the starting iridium complex (Equation 10). It has been demonstrated that $(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\left(\mathrm{N}_{2}\right)$ is not easily isolated or observed experimentally and, computationally, the release of nitrogen from hydrogen has been determined as very accessible.

Kinetic analysis of the reaction scheme of Equations 6 through 10 is presented in the supplemental material. This kinetic analysis leads to determination of the rate determining step $k_{l}$ value for this reaction, the release of the first equivalent of ammonia (Equation 7). Four experiments were conducted at two catalyst concentrations, and the average first order rate constant was determined to be $9.4 \times 10^{-3} \mathrm{~min}^{-1}$ (Table 3). Overall, the consumption rate of hydrazine and the formation rate of ammonia corresponding to Equation 4 (at least, at the early stages) are both zero-order reactions with respect to the hydrazine concentration and are first-order reactions with respect to the initial $(\mathrm{PCP}) \mathrm{IrH}_{2}$ concentration.

Table 6.6 Values of $\mathrm{k}_{1}$, the Rate Constant for the Release of $\mathrm{NH}_{3}$ from $\mathbf{2 a}$ (Equation 7)

| Experiment | $\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ}$ | $k_{1}, \min ^{-1}$ |
| :---: | :---: | :---: |
| 1 | 0.01 | $9.8 \cdot 10^{-3}$ |
| 2 | 0.01 | $9.4 \cdot 10^{-3}$ |
| 3 | 0.02 | $9.4 \cdot 10^{-3}$ |
| 4 | 0.02 | $9.0 \cdot 10^{-3}$ |

### 6.2.8 Discussion of Proposed Mechanism

A mechanism is proposed in accordance with the experimental results discussed above (Figure 6.4). The proposed mechanism starts with the formation of $\mathbf{6 - 2} \mathbf{a}$ upon addition of hydrazine to (PCP) $\mathrm{IrH}_{2}$. The first half of the mechanism is the hydrogenation of hydrazine to release two equivalents of $\mathrm{NH}_{3}$ while
the second half of the mechanism is the dehydrogenation to form $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$. The two halves of the reaction mechanism will be discussed in more detail below supported by DFT calculations (Figures 6.5 and 6.6 respectively).

Figure 6.4 Proposed Mechanism for the Catalytic Synthesis of Ammonia, Nitrogen and Hydrogen

Figure 6.5 Proposed Pathway for the Hydrogenation of Hydrazine to Form Ammonia, Nitrogen and Hydrogen

The hydrogenation pathway starts after addition of hydrazine to ( PCP ) $\mathrm{IrH}_{2}$ to yield 6-2a, calculated to be downhill by $4.7 \mathrm{kcal} / \mathrm{mol}$. The following three steps detail possible rate determining steps. First, transfer of hydrogen from the $\alpha-\mathrm{N}$ of hydrazine to an iridium hydride gives complex II. Subsequent transfer of hydrogen to the $\beta$-N gives III. The dihydrogen ligand has multiple degrees of freedom and can easily rotate, thereby either of the hydrogens can be involved in the transfer. Finally, release of the first equivalent of ammonia yields IV. The two hydrogen transfers and the $\mathrm{N}-\mathrm{N}$ bond cleavage each have an energy barrier of approximately $30 \mathrm{kcal} / \mathrm{mol}$. If release of ammonia is rate determining, then less sterically hindered ( ${ }^{\text {Pr } 4} \mathrm{PCP}$ )Ir catalyst would be less likely to release $\mathrm{NH}_{3}$ due to a high energy barrier or high stability of the four coordinate complex. The less sterically hindered catalyst presumably binds much more strongly to ammonia and therefore the reaction is much slower. As was observed experimentally, the ( ${ }^{\text {Prr4 }} \mathrm{PCP}$ )Ir catalyst is much less active. Transfer of a hydrogen from the iridium center in IV yields $\mathbf{V}$, which has been characterized at $-30{ }^{\circ} \mathrm{C} .{ }^{23}$ Hydrogen transfer via TS-V-VI yields VI, which has also been characterized at room temperature (refer to Scheme 6.1). An energy difference of $2 \mathrm{kcal} / \mathrm{mol}$ and an energy of $-11 \mathrm{kcal} / \mathrm{mol}$ for $\mathbf{T S}-\mathbf{V}-\mathbf{V I}$ are in accordance with previous experiments which have shown that $\mathbf{V}$ easily transitions to VI, as it is the thermodynamically preferred product. Neither $\mathbf{V}$ nor VI was observed during the transformation of hydrazine to ammonia. The release of ammonia from VI gives the second equivalent of ammonia allowing for addition of a second hydrazine molecule to the $14 \mathrm{e}^{-}$fragment to generate $\mathbf{6 - 1}$.

This concludes the first half or hydrogenation portion of the catalytic cycle and leads to the dehydrogenation of hydrazine (Figure 6.6).

Figure 6.6 Proposed Pathway for the Dehydrogenation of Hydrazine to Form Nitrogen and Hydrogen

$\mathrm{N}-\mathrm{H}$ activation and subsequent transfer of two hydrogens to the iridium center leads to a side-on diazene intermediate (VIII). Diazene intermediates have been cited in many references as a critical intermediate during the synthesis of ammonia from nitrogen and hydrogen. ${ }^{34,66,67}$ Subsequent hydrogen transfers to the metal center from the diazene intermediate and loss of hydrogen gives the dihydride dinitrogen complex ( $\mathbf{X}$ ). Nitrogen release from $\mathbf{X}$ to give the dihydride complex and addition of a second molecule of hydrazine leads back to the start of the catalytic cycle. The reaction barrier for the dehydrogenation reaction is $22.4 \mathrm{kcal} / \mathrm{mol}$ and the reaction is exothermic as $\Delta \mathrm{G}=-52.8 \mathrm{kcal} / \mathrm{mol}$.

Overall, the process has been calculated to be extremely thermodynamically downhill, with $\Delta \mathrm{G}=$ - $80.7 \mathrm{kcal} / \mathrm{mol}$. The thermodynamic driving force for this reaction comes from entropic considerations $\left(2 \mathrm{~N}_{2} \mathrm{H}_{4}\right.$ going to $2 \mathrm{NH}_{3}, \mathrm{~N}_{2}$, and $\left.\mathrm{H}_{2}\right)$ and the formation of products that are more stable. The reverse reaction $\left(2 \mathrm{NH}_{3}, \mathrm{~N}_{2}\right.$, and $\mathrm{H}_{2}$ going to $\left.2 \mathrm{~N}_{2} \mathrm{H}_{4}\right)$ would require upwards of $111 \mathrm{kcal} / \mathrm{mol}$. The overall reaction barrier is $30 \mathrm{kcal} / \mathrm{mol}$. Only one other case of hydrogenative $\mathrm{N}-\mathrm{N}$ bond cleavage has been reported for a pincer complex. ${ }^{42}$ In this case, the hydrogen source is $\mathrm{H}_{2}$, while, in the proposed mechanism discussed above for (PCP) $\mathrm{IrH}_{2}$ (Figure 6.4), the source is hydrazine itself. This proposed mechanism also differs
from the proposed mechanism by Hartwig for the formation of ammonia via substituted hydrazine as there is no potential for C-H activation. As such, N-H activation of hydrazine can lead to $\mathrm{N}-\mathrm{N}$ bond cleavage and evolution of $\mathrm{NH}_{3}$.

### 6.2.9 Reaction with Hydrazine Sulfate, Azobenzene and Azo-tert-butane

Hydrazine sulfate is another source of hydrazine and is often easier to handle as it is a powder at room temperature. (PCP) $\mathrm{IrH}_{2}$ was reacted with hydrazine sulfate and sodium tert-butoxide in $p$-xylene- $d_{10}$ and no reaction was observed at room temperature as expected, yet upon heating at $100{ }^{\circ} \mathrm{C}$ for 20 hours, $\mathbf{6 - 3}$ is observed as the major product and free ammonia is observed by ${ }^{1} \mathrm{H}$ NMR spectroscopy.

Scheme 6.10 Reaction with Hydrazine Sulfate

In attempts to isolate a diazene intermediate proposed in Figure 6.6, azobenzene was reacted with either the $14 \mathrm{e}^{-}(\mathrm{PCP}) \mathrm{Ir}$ or $(\mathrm{PCP}) \mathrm{IrH}_{2}$ at room temperature, which generates two $\mathrm{C}-\mathrm{H}$ activation product isomers in a $2: 1$ ratio (6-5: 6-6, Scheme 6.11). The isomer in which the $\mathrm{C}-\mathrm{H}$ activated phenyl ring is trans to the hydride and the azo is trans to PCP aryl ring (6-5) is the major isomer. The ${ }^{31} \mathrm{P}$ NMR spectrum shows two signals at 55.7 ppm for the major isomer and 52.3 ppm for the minor isomer. The ${ }^{1} \mathrm{H}$ NMR spectrum shows two triplets in the hydride region at -9.4 ppm and -18.5 ppm , each integrating to one proton with respect to the integrated $36{ }^{t}$ butyl protons. These isomers are similar to the final product for the addition of methylphenylhydrazine $\left(\mathrm{MePhNNH}_{2}\right)$ to the (PCP)Ir fragment isolated by Hartwig (Scheme 6.2), as well as other examples in the literature. ${ }^{62,68}$ However, in these reported examples, C-H activation occurs first, followed by nitrogen coordination.

Scheme 6.11 Reaction with Azobenzene

When present, C-H bonds will be activated by (PCP)Ir preferentially over the coordination of dinitrogen. ${ }^{69}$ In the presence of $\mathrm{N}_{2} \mathrm{H}_{2}$ without any C-H aryl bonds, a diazene complex, either side-on or end-on, or the $\mathrm{N}-\mathrm{H}$ activation of diazene would be preferential. In an attempt to eliminate any potential CH activation of R substituents, ( PCP ) $\mathrm{IrH}_{2}$ was reacted with azo-tert-butane, however no reaction was observed presumably due to the large steric hindrance of the bulky ${ }^{t}$ butyl groups. Complexes 6-5 and 6-6 give some evidence that diazene can be activated and supported by a (PCP)Ir complex, but dissociation to nitrogen and hydrogen would be energetically downhill and so isolation of a non-substituted diazene complex would be unlikely.

### 6.3 Closing

Various (PCP)Ir pincer hydrazine complexes have been characterized. The main complex $\left((\mathrm{PCP}) \mathrm{IrH}_{2} \mathrm{~N}_{2} \mathrm{H}_{4}\right)$ can undergo both dehydrogenation to form nitrogen and hydrogen as well as an $\mathrm{N}-\mathrm{N}$ bond cleavage to form ammonia, nitrogen and hydrogen. The dehydrogenation reaction occurred under vacuum with a calculated $\Delta \mathrm{G}$ of $-42 \mathrm{kcal} / \mathrm{mol}$. While the release of $\mathrm{NH}_{3}$ is favored thermodynamically ( $\Delta \mathrm{G}$ $=-80 \mathrm{kcal} / \mathrm{mol}$ ), is only observed under catalytic conditions. Kinetically, the reaction indeed conforms to a zero-order reaction with respect to the concentration of hydrazine and first-order with respect to the initial (PCP) $\mathrm{IrH}_{2}$ concentration, with a single kinetic parameter, $k_{1}$, characterizing concentrations of hydrazine and ammonia. DFT calculations support a mechanism in which the hydrogen transfer from hydrazine to iridium, and vice versa, is an important feature in both the hydrogenation and dehydrogenation pathways.

### 6.4 Experimental

## General Methods

All reactions were performed under an argon atmosphere unless specified using standard Schlenck techniques or in an argon-filled glove box. $\mathrm{C}_{6} \mathrm{H}_{6}, \mathrm{C}_{6} \mathrm{D}_{6}$, and $p$-xylene- $d_{10}$ were either dried over $\mathrm{Na} / \mathrm{K}$ alloy and collected via vacuum transfer or stirred over activated alumina for 48 hours, filtered, and then stored over molecular sieves. Norbornene (NBE) was sublimed before use. Hydrazine was purchased from Aldrich as 1 M solution in THF. $\mathrm{NH}_{3}$ was purchased from Aldrich as 0.1 M solution in THF. All other substrates were degassed before entry to glovebox and used without further purification. $\left({ }^{t \mathrm{Bu} 4} \mathrm{PCP}\right) \operatorname{Ir}(\mathrm{H})(\mathrm{Ph}),{ }^{50} \quad\left({ }^{(\mathrm{Bu} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2},{ }^{70} \quad\left({ }^{\mathrm{tBu} 4} \mathrm{PCP}\right) \mathrm{IrHCl}^{21} \quad\left({ }^{7 \mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2},{ }^{57} \quad(\mathrm{POCOP}) \mathrm{IrH}_{2},{ }^{40} \quad$ and $\left({ }^{\text {iPr4 }} \mathrm{PCOP}\right) \mathrm{IrH}_{2}{ }^{63}$ were synthesized according to literature. ${ }^{1} \mathrm{H}$ and ${ }^{31} \mathrm{P}$ NMR spectra were obtained from either a 400 or 500 MHz Varian instrument. The residual peak of the deuterated solvent was used as a reference for all ${ }^{1} \mathrm{H}$ NMR spectra and an internal capillary standard of $\mathrm{PMe}_{3}$ in $p$-xylene- $d_{10}(-62.4 \mathrm{ppm})$ was used to reference ${ }^{31} \mathrm{P}$ NMR chemical shifts.

## (PCP) $\mathbf{I r N}_{2} \mathbf{H}_{4}, \mathbf{6 - 1}$

To a $0.5 \mathrm{~mL} p$-xylene- $d_{10}$ solution of 8.9 mg catalyst ( $15 \mu \mathrm{~mol}$ ) in a J. Young NMR tube, $3 \mu \mathrm{~L}$ of 5 M NBE in $p$-xylene- $d_{10}$ stock solution $(16 \mu \mathrm{~mol})$ and $2.1 \mu \mathrm{~L} \mathrm{C}_{6} \mathrm{H}_{6}(23.5 \mu \mathrm{~mol})$ were added to generate $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})(\mathrm{Ph})$ in situ. To this mixture, $46 \mu \mathrm{~L}$ of 1 M hydrazine in THF $(46 \mu \mathrm{~mol})$ was added to the solution. The solution changed to orange in color and formed the title complex in situ. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$ -xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 68.9\left(\mathrm{~s},(P C P) \mathrm{IrN}_{2} \mathrm{H}_{4}\right) .{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{~ M H z}\right): \delta 7.06\left(\mathrm{~d}, \boldsymbol{J}_{H H}=7.2\right.$ $\left.\mathrm{Hz}, 2 \mathrm{H}, \operatorname{Ar}-H), 6.87\left(\mathrm{t}, J_{H H}=7.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ar}-H\right), 4.8\left(\mathrm{bs}, 2 \mathrm{H}, \beta-\mathrm{NH}_{2}\right), 3.24(\mathrm{t}, 2 \mathrm{H}, \alpha-\mathrm{NH})_{2}\right), 2.95(\mathrm{t}, 4 \mathrm{H}$, $\left.\mathrm{CH}_{2} \mathrm{P}\right), 1.34\left(\mathrm{t}, J_{P H}=6.4 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right)$.

## (PCP) $\mathbf{I r H}_{2} \mathbf{N}_{2} \mathrm{H}_{4}, \mathbf{6 - 2 a}$

To a solution of $5 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrH}_{2}(8.5 \mu \mathrm{~mol})$ in $p$-xylene, $46 \mu \mathrm{~L}$ of a 1 M hydrazine in THF solution ( $46 \mu \mathrm{~mol}$ ) was added in a J. Young NMR tube. The solution immediately changed color from dark red to pale yellow. The solvent was removed slowly under reduced pressure to give a pale yellow solid. The solid was redissolved in $p$-xylene- $d_{10}$ and NMR spectroscopy showed quantitative conversion to the product. Crystals suitable for X-ray crystallography were grown from a pentane/p-xylene solution
containing excess hydrazine in THF. X-ray crystallography refinement and structure parameters are included in Tables 6.7 through 6.11. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 66.2\left(\mathrm{~s},(P C P) \operatorname{IrH}_{2} \mathrm{~N}_{2} \mathrm{H}_{4}\right) .{ }^{\mathbf{1}} \mathbf{H}$ NMR (p-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{M H z}\right): \delta 6.83\left(\mathrm{~d}, J_{H H}=7.0 \mathrm{~Hz}, 2 \mathrm{H}, \operatorname{Ar-}-H\right), 6.75\left(\mathrm{t}, J_{H H}=7.5 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ar}-H\right), 3.81$ $\left(\mathrm{s}, 2 \mathrm{H}, \beta-\mathrm{NH}_{2}\right), 3.16\left(\mathrm{t}, J_{H H}=3.2 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.95\left(\mathrm{t}, J_{H H}=3.6 \mathrm{~Hz}, 2 \mathrm{H}, \alpha-\mathrm{NH} H_{2}\right), 1.32\left(\mathrm{t}, J_{P H}=4.8 \mathrm{~Hz}\right.$, $\left.36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right),-8.74\left(\mathrm{t}, J_{P H}=11.6 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ir}-\mathrm{H}_{2}\right)$.

## (PCP) $\operatorname{IrHCl}\left(\mathrm{H}_{2} \mathbf{N}_{2} \mathrm{H}_{2}\right), \mathbf{6 - 2 b}$

To a solution of $5.8 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrHCl}$ in $\mathrm{C}_{6} \mathrm{D}_{6}, 46 \mu \mathrm{~L}$ of 1 M hydrazine in THF solution ( $46 \mu \mathrm{~mol}$ ) was added. The solution changed from orange to golden yellow. The product precipitates from solution as yellow solid within ten minutes. ${ }^{31} \mathbf{P}$ NMR $\left(\boldsymbol{p}\right.$-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 50.3\left(\mathrm{~s},(P C P) \operatorname{IrHCl}\left(\mathrm{H}_{2} \mathrm{~N}_{2} \mathrm{H}_{2}\right)\right)$. ${ }^{1} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{~ M H z}$ ): $\delta 6.85(\mathrm{t}, 1 \mathrm{H}, \mathrm{Ar}-H), 6.83(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}-H), 4.24(\mathrm{bs}, 2 \mathrm{H}, \beta-\mathrm{N} H), 4.06$ (bs, $2 \mathrm{H}, \alpha-\mathrm{NH}_{2}$ ), $3.25\left(\mathrm{~d}\right.$ of vt, $2 \mathrm{H}, C \mathrm{H}_{2} \mathrm{P}$ ), $3.13\left(\mathrm{~d}\right.$ of vt, $2 \mathrm{H}, C H_{2} \mathrm{P}$ ), $1.56\left(\mathrm{t}, J_{P H}=6.2 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right), 1.50$ $\left(\mathrm{t}, J_{P H}=6.2 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right),-21.19(\mathrm{bs}, 1 \mathrm{H}, \mathrm{Ir}-H)$.

## (PCP) IrH $_{2} \mathbf{P h H N}_{2} \mathrm{H}_{\mathbf{2}}, \mathbf{6 - 2} \mathbf{c}$

To a solution of $5 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrH}_{2}(8.5 \mu \mathrm{~mol})$ in $p$-xylene, $1 \mu \mathrm{~L} \mathrm{PhHNNH}_{2}(8.5 \mu \mathrm{~mol})$ was added in a J. Young NMR tube. The solution immediately changed color from dark red to pale yellow. The solvent is removed slowly under reduced pressure to give a pale yellow solid. The solid was redissolved in $p$ -xylene- $d_{l 0}$ and NMR spectroscopy showed quantitative conversion to the product. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{10}$, 161.9 MHz): $\delta 66.6\left(\mathrm{~s},(P C P) \operatorname{IrH}_{2} \mathrm{PhHN}_{2} \mathrm{H}_{2}\right) .{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{~ M H z}\right): \delta 6.81(\mathrm{~d}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H})$, $6.94\left(\mathrm{t}, J_{H H}=9.6 \mathrm{~Hz}, 2 \mathrm{H}\right.$, phenyl $\left.\mathrm{NHNH}_{2}\right), 6.81(\mathrm{~d}, 2 \mathrm{H}, \operatorname{Ar}-H), 6.78\left(\mathrm{t}, J_{H H}=7.6 \mathrm{~Hz}, 1 \mathrm{H}\right.$, phenyl $\left.\mathrm{NHNH}_{2}\right)$, $6.74(\mathrm{t}, 1 \mathrm{H}, \operatorname{Ar}-H), 6.22\left(\mathrm{~d}, J_{H H}=7.6 \mathrm{~Hz}, 2 \mathrm{H}\right.$, phenyl $\left.\mathrm{NHNH}_{2}\right), 5.20(\mathrm{bs}, 1 \mathrm{H}, \beta-\mathrm{N} H), 3.42\left(\mathrm{bs}, 2 \mathrm{H}, \alpha-\mathrm{N} H_{2}\right)$, $3.17\left(\mathrm{t}, J_{H H}=3.6 \mathrm{~Hz}, 4 \mathrm{H}, C H_{2} \mathrm{P}\right), 1.35\left(\mathrm{t}, J_{P H}=6 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2}\right),-8.50\left(\mathrm{t}, J_{P H}=14.8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ir}-H_{2}\right)$.

## (PCP) $\mathbf{I r H C l}\left(\mathbf{P h H N}_{2} \mathbf{H}_{2}\right), \mathbf{6 - 2 d}$

To a solution of $5.8 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrHCl}$ in $\mathrm{C}_{6} \mathrm{D}_{6}, 0.9 \mu \mathrm{~L} \mathrm{PhHNNH}_{2}$ was added. The solution changed from orange to golden yellow. The product precipitated from solution as yellow solid after the solution was allowed to sit for at least 30 minutes. ${ }^{\mathbf{3 1}} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 47.8$ (s, $\left.(P C P) \operatorname{IrHCl}\left(\mathrm{PhHN}_{2} \mathrm{H}_{2}\right)\right) .{ }^{\mathbf{1}} \mathbf{H}$ NMR $\left(\boldsymbol{p}\right.$-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{~ M H z}\right): \delta 7.14\left(\mathrm{bs}, 2 \mathrm{H}\right.$, phenyl $\left.\mathrm{NHNH}_{2}\right), 6.68(\mathrm{bt}, 1 \mathrm{H}$,
phenyl $\mathrm{NHNH}_{2}$ ), 6.24 (bs, 2H, pheny $\mathrm{NHNH}_{2}$ ) $5.44(\mathrm{bs}, 1 \mathrm{H}, \beta-\mathrm{NH}), 4.18$ (bs, $2 \mathrm{H}, \alpha-\mathrm{NH}_{2}$ ), 2.94 (bs, 4 H , $\left.C H_{2} \mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2}\right), 1.25\left(\mathrm{t}, J_{P H}=6 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right),-22.06(\mathrm{bs}, 1 \mathrm{H}, \mathrm{Ir}-H)$.

## (PCP) $\mathbf{I r H}_{\mathbf{2}}\left(\mathbf{N H}_{\mathbf{3}}\right), \mathbf{6 - 3}$

To a solution of $5 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrH}_{2}(8.5 \mu \mathrm{~mol})$ in $p$-xylene- $d_{10}, 90 \mu \mathrm{~L}$ of a $0.5 \mathrm{M} \mathrm{NH}_{3}$ in THF solution ( $46 \mu \mathrm{~mol}$ ) was added in a J. Young NMR tube. The solution immediately changed color from dark red to pale orange upon mixing. NMR spectroscopy showed quantitative conversion to the product. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\left.\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}\right): \delta 67.2\left(\mathrm{~s},(P C P) \mathrm{IrH}_{2}\left(\mathrm{NH}_{3}\right)\right) .{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{M H z}$ ): $\delta$ $6.79\left(\mathrm{~d}, J_{H H}=7.5 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-H\right), 6.67\left(\mathrm{t}, J_{H H}=7.3 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ar}-H\right), 3.10\left(\mathrm{t}, J_{H H}=3.5 \mathrm{~Hz}, 4 \mathrm{H}, C H_{2} \mathrm{P}^{\mathrm{t}} \mathrm{Bu}_{2}\right)$, $2.2\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{NH} H_{3}\right), 1.35\left(\mathrm{t}, J_{P H}=5.8 \mathrm{~Hz}, 36 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}_{2}\right),-8.75\left(\mathrm{t}, J_{P H}=14.8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ir}-H_{2}\right)$.

## $\left({ }^{(\mathrm{Pr} 4} \mathbf{P C P}\right) \mathrm{IrH}_{2} \mathbf{N}_{2} \mathrm{H}_{4}, \mathbf{6 - 4}$

To a solution of $5 \mathrm{mg}\left({ }^{(\mathrm{Pr} 4} \mathrm{PCP}\right) \mathrm{IrH}_{2}(8.5 \mu \mathrm{~mol})$ in $p$-xylene, $46 \mu \mathrm{~L}$ of a 1 M hydrazine in THF solution ( $46 \mu \mathrm{~mol}$ ) was added in a J. Young NMR tube. The solution immediately changed color from dark red to pale yellow. The solvent is removed slowly under reduced pressure to give a pale yellow solid. The solid was redissolved in $p$-xylene $-d_{10}$ and NMR spectroscopy showed quantitative conversion to the product. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{1 6 1 . 9} \mathbf{~ M H z}$ ): $\delta 53.8\left(\mathrm{~s},\left({ }^{i \mathrm{Pr} 4} P C P\right) \mathrm{IrH}_{2} \mathrm{~N}_{2} \mathrm{H}_{4}\right) .{ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}$, $400 \mathrm{MHz}): \delta 6.86\left(\mathrm{~d}, J_{H H}=7.0 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-H\right), 6.80\left(\mathrm{t}, J_{H H}=6.5 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ar}-H\right), 3.70\left(\mathrm{bs}, 2 \mathrm{H}, \beta-\mathrm{NH}_{2}\right)$, $\left.3.03\left(\mathrm{t}, J_{H H}=4.0 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{P}\right), 2.99\left(\mathrm{t}, J_{H H}=4.0 \mathrm{~Hz}, 2 \mathrm{H}, \alpha-\mathrm{NH}\right)_{2}\right), 1.91\left(\mathrm{~m}, 4 \mathrm{H}, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.23\left(\mathrm{qt}, J_{P H}\right.$ $\left.=7.5 \mathrm{~Hz}, 12 \mathrm{H}, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right), 1.11\left(\mathrm{qt}, J_{P H}=6.0 \mathrm{~Hz}, 12 \mathrm{H}, \mathrm{PCH}\left(\mathrm{CH}_{3}\right)_{2}\right),-9.25\left(\mathrm{t}, J_{P H}=16.0 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ir}-\mathrm{H}_{2}\right)$.

## $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})($ Azobenzene) cis and trans isomers, 6-5 and 6-6

Method 1: To a $0.5 \mathrm{~mL} p$-xylene- $d_{10}$ solution of $5.2 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrH}_{2}(15 \mu \mathrm{~mol})$ in a J. Young NMR tube, excess NBE was added, followed by addition of 4.1 mg azobenzene ( $23 \mu \mathrm{~mol}$ ). Method 2: To a 0.5 $\mathrm{mL} p$-xylene- $d_{10}$ solution of $5.0 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrH}_{2}(15 \mu \mathrm{~mol})$ in a J . Young NMR tube 2.0 mg azobenzene (11 $\mu \mathrm{mol}$ ) was added. In both methods, the solution changed from red to dark brown. Complexes 6-5 (CisAzo) and 6-6 (Trans-Azo) were obtained in a 2:1 ratio and characterized in situ. ${ }^{31} \mathbf{P}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}$, $\mathbf{1 6 1 . 9} \mathbf{M H z}$ ): $\delta 55.8$ ( s , Cis-Azo), 52.3 (s, Trans-Azo). ${ }^{\mathbf{1}} \mathbf{H}$ NMR ( $\boldsymbol{p}$-xylene- $\boldsymbol{d}_{\mathbf{1 0}}, \mathbf{4 0 0} \mathbf{M H z}$ ): $\delta 8.74\left(\mathrm{t}, \boldsymbol{J}_{H H}=\right.$ $8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{PCP}$ aryl cis-azo), $8.63\left(\mathrm{~d}, J_{H H}=8 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{PCP}\right.$ aryl cis-azo), $7.69(\mathrm{~d}, 1 \mathrm{H}, \mathrm{Ar}-H), 7.3-7.1$ (Ar$H), 7.92\left(\mathrm{t}, J_{H H}=8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{PCP}\right.$ aryl trans-azo), $3.38\left(\mathrm{dt}, J_{H H}=4 \mathrm{~Hz}, \mathrm{~J}_{\mathrm{PH}}=16 \mathrm{~Hz}, 2 \mathrm{H}\right.$, trans-azo), 3.24 (dt,
$J_{H H}=4 \mathrm{~Hz}, \mathrm{~J}_{\mathrm{PH}}=16 \mathrm{~Hz}, 2 \mathrm{H}$, cis-azo $), 3.13\left(\mathrm{dt}, J_{H H}=4 \mathrm{~Hz}, \mathrm{~J}_{\mathrm{PH}}=16 \mathrm{~Hz}, 2 \mathrm{H}\right.$, trans-azo $), 3.05\left(\mathrm{dt}, J_{H H}=4\right.$ $\mathrm{Hz}, J_{P H}=16 \mathrm{~Hz}, 2 \mathrm{H}$ cis-azo $), 1.26\left(\mathrm{t}, J_{P H}=6 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right.$, trans-azo $), 1.18\left(\mathrm{t}, J_{P H}=8 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right.$, cis-azo), $0.57\left(\mathrm{t}, J_{P H}=6 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right.$, trans-azo $), 0.52\left(\mathrm{t}, J_{P H}=4 \mathrm{~Hz}, 18 \mathrm{H}, \mathrm{P}^{t} \mathrm{Bu}\right.$, cis-azo $),-9.35\left(\mathrm{t}, J_{P H}=\right.$ $20.0 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ir}-H$, cis-azo $),-18.45\left(\mathrm{t}, J_{P H}=20.0 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ir}-H\right.$, trans-azo $)$.

## Low Temperature NMR spectroscopy

To a 0.4 mL mesitylene- $d_{12}$ solution of 5.2 mg catalyst ( $\left.\sim 8.5 \mu \mathrm{~mol}\right)$ in a J. Young NMR tube, 1.5 mg NBE and $\mathrm{C}_{6} \mathrm{H}_{6}$ were added to generate $(\mathrm{PCP}) \operatorname{Ir}(\mathrm{H})(\mathrm{Ph})$ in situ. The sample was cooled in a $-45^{\circ} \mathrm{C}$ glovebox freezer for ten minutes. The sample was removed from the freezer $46 \mu \mathrm{~L}$ hydrazine ( $46 \mu \mathrm{~mol}$ ) was added immediately. Upon removal from an argon glove box, the sample was immediately frozen in a liquid nitrogen bath. The NMR instrument was pre-chilled and the sample was inserted into a - $30^{\circ} \mathrm{C}$ NMR instrument. Both ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectra were obtained at $-30,-20,-10,0,10$ and $25{ }^{\circ} \mathrm{C}$.

## Catalytic Conversion of $\mathbf{N}_{\mathbf{2}} \mathbf{H}_{\mathbf{4}}$ to $\mathbf{N H}_{\mathbf{3}}$

To a $0.5 \mathrm{~mL} p$-xylene- $d_{10}$ solution of 5 mg catalyst $(\sim 8.5 \mu \mathrm{~mol})$ in a J. Young NMR tube, $46 \mu \mathrm{~L}$ 1 M hydrazine in THF ( 46 mmol ) was added. The solution changed from dark red to yellow instantaneously. The solution was heated in a $100{ }^{\circ} \mathrm{C}$ oil bath. During heating, the solution changed from pale yellow to dark green and upon completion changed to red. Upon cooling and mixing, the red solution changed to a bright yellow. Reaction progress was monitored at different time intervals by NMR spectroscopy. Concentration of ammonia was determined via integration correlated to the known concentration of an internal $\mathrm{PMe}_{3}$ capillary standard.

## Catalytic Conversion of $\mathbf{N}_{2} \mathbf{H}_{4}$ to $\mathbf{N H}_{3}$ under a hydrogen atmosphere

The catalyst was dissolved in $450 \mu \mathrm{~L} p$-xylene- $d_{10}$ and $50 \mu \mathrm{~L} 1 \mathrm{M}$ hydrazine in THF solution (50 $\mu \mathrm{mol}$ ) was then added. The solution was transferred to J. Young NMR tube and 1 atm hydrogen was added after the solution was degassed. The solution was heated in a $100^{\circ} \mathrm{C}$ oven while the solution was mixed used a rotary motor. Reaction was monitored periodically by NMR spectroscopy. The concentration of ammonia was determined by integration of the proton NMR signal, calibrated by the known concentration of the $\mathrm{PMe}_{3}$ capillary standard.

## Exchange Equilibrium between $\mathbf{N}_{2} \mathbf{H}_{4}$ and $\mathrm{PEt}_{3}$

To a $0.5 \mathrm{~mL} p$-xylene- $\mathrm{d}_{10}$ solution of $5.6 \mathrm{mg}(\mathrm{PCP}) \mathrm{IrH}_{2}(9.5 \mu \mathrm{~mol})$ in an NMR tube, $46 \mu \mathrm{~L}$ hydrazine $(46 \mu \mathrm{~mol})$ and $1.3 \mu \mathrm{~L} \mathrm{PEt}_{3}(8.8 \mu \mathrm{~mol})$ were added. The NMR tube was sealed under an argon atmosphere and the solution was monitored by ${ }^{31} \mathrm{P}$ and ${ }^{1} \mathrm{H}$ NMR spectroscopy. The concentration of each species was determined by integration of each ${ }^{31} \mathrm{P}$ NMR shift or integration of each hydride shift in correlation to the known concentration of added species and to the known concentration of an internal standard. Characterization of (PCP) $\mathrm{IrH}_{2} \mathrm{PEt}_{3}$ has been previously published. ${ }^{72}$

## Kinetics experiments

0.01 M or 0.02 M catalyst was dissolved in $450 \mu \mathrm{~L} p$-xylene- $d_{10}$ and $50 \mu \mathrm{~L}$ hydrazine in THF was added to the solution. The solution was transferred to J. Young NMR tube and heated in a $100{ }^{\circ} \mathrm{C}$ oven while mixed by a rotary motor. Reaction was monitored at different time intervals by NMR spectroscopy. The concentration of ammonia was determined by integration of the proton NMR signal, calibrated by the known concentration of the $\mathrm{PMe}_{3}$ capillary standard.

## Computational Details

DFT calculations were completed by Tian Zhou. All calculations used DFT methodologies as implemented by the Gaussian $09^{73}$ computer program. All the data presented here results from calculations using the $\mathrm{TPSS}^{74}$ set of functionals but M06 ${ }^{75}$ and $\mathrm{PBE}^{76}$ functionals were also examined, giving similar results. The Hay-Wadt relativistic effective (small) core potential ${ }^{77}$ and the LANL2TZ basis set ${ }^{78}$ augmented by a diffuse d-type function (exponent $=0.07645)^{79}$ was utilized for Ir atom, and all other atoms $(\mathrm{P}, \mathrm{N}, \mathrm{C}$, and H$)$ were treated with the $6-311 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis sets. ${ }^{80}$ All the geometries and potential energies were calculated for all the stationary points along the reaction paths by standard optimization procedures. Normal mode analysis was performed to further verify the nature of a particular stationary point (intermediate or transition state). The resulting set of vibrational frequencies was employed (without scaling) to determine zero-point energy corrections. Enthalpies $\left(\Delta H, \Delta H^{\dagger}\right)$ and Gibbs free energies $(\Delta G$, $\left.\Delta \mathrm{G}^{\ddagger} ; \mathrm{T}=298.15 \mathrm{~K}, \mathrm{P}=1 \mathrm{~atm}\right)$ were subsequently obtained from the potential energies $\left(\Delta \mathrm{E}, \Delta \mathrm{E}^{\dagger}\right)$ using standard thermodynamic corrections. ${ }^{81}$ In order to enhance computational stability and accuracy ${ }^{82}$ in geometry optimization and normal calculations, an increased atomic grid sizes setting (grid $=$ ultrafine option) was utilized. ${ }^{83}$

## Derivation of kinetic equations

Gross reaction:

$$
\begin{equation*}
2 \mathrm{~N}_{2} \mathrm{H}_{4} \rightarrow 2 \mathrm{NH}_{3}+\mathrm{N}_{2}+\mathrm{H}_{2} \tag{1}
\end{equation*}
$$

Initial Reaction:

$$
\begin{equation*}
(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)+\mathrm{N}_{2} \mathrm{H}_{4} \rightarrow(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)-\mathrm{N}_{2} \mathrm{H}_{4} \tag{2}
\end{equation*}
$$

Reaction Set:

$$
\begin{align*}
& \operatorname{PCPIr}\left(\mathrm{H}_{2}\right)-\mathrm{N}_{2} \mathrm{H}_{4}-\left(k_{1}\right) \rightarrow(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)=\mathrm{NH}+\mathrm{NH}_{3}  \tag{3}\\
& (\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)=\mathrm{NH}+\mathrm{N}_{2} \mathrm{H}_{4}-\left(k_{2}\right) \rightarrow \quad(\mathrm{PCP}) \operatorname{Ir}-\mathrm{N}_{2} \mathrm{H}_{4}+\mathrm{NH}_{3}  \tag{4}\\
& (\mathrm{PCP}) \operatorname{Ir}-\mathrm{N}_{2} \mathrm{H}_{4}-\left(k_{3}\right) \rightarrow(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)-\mathrm{N}=\mathrm{N}+\mathrm{H}_{2}  \tag{5}\\
& (\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)-\mathrm{N}=\mathrm{N}+\mathrm{N}_{2} \mathrm{H}_{4}-\left(k_{4}\right) \rightarrow(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)-\mathrm{N}_{2} \mathrm{H}_{4}+\mathrm{N}_{2} \tag{6}
\end{align*}
$$

[Ir] balance:
$\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2} \mathrm{H}_{4}\right]+\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{NH}_{3}\right]=\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ}$.
Because $\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)-\mathrm{NH}_{3}\right] \ll\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)-\mathrm{N}_{2} \mathrm{H}_{4}\right]$ during most of the reaction:

$$
\begin{equation*}
\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2} \mathrm{H}_{4}\right] \approx\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \text { and }\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]_{\text {start }}=\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]^{\circ}-\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \tag{7}
\end{equation*}
$$

The steady-state approach to kinetics of the multi-stage reaction (Reactions 3-6)
Equations 1 and 4

$$
\begin{equation*}
d\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2} \mathrm{H}_{4}\right] / d t=-k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2} \mathrm{H}_{4}\right]+k_{4} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2}\right]\left[\mathrm{N}_{2} \mathrm{H}_{4}\right] \approx 0 \tag{8}
\end{equation*}
$$

Since $\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2} \mathrm{H}_{4}\right] \approx\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ}$, then:
$\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2}\right] \approx k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} /\left(k_{4} \cdot\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]\right)$
Equations 3 and 4

$$
\begin{gathered}
d\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2}\right] / d t=k_{3} \cdot\left[(\mathrm{PCP}) \operatorname{IrN}_{2} \mathrm{H}_{4}\right]-k_{4} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2}\right] \cdot\left[\mathrm{N}_{2} \mathrm{H}_{4}\right] \approx 0 \\
{\left[(\mathrm{PCP}) \operatorname{IrN}_{2} \mathrm{H}_{4}\right] \approx k_{4} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2}\right]\left[\mathrm{N}_{2} \mathrm{H}_{4}\right] / k_{3}=}
\end{gathered}
$$

Substitution of Equation 9

$$
\begin{equation*}
\left[(\mathrm{PCP}) \mathrm{IrN}_{2} \mathrm{H}_{4}\right] \approx k_{4} \cdot k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{IrH}_{2}\right]^{\circ} /\left(k_{4} \cdot\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]\right)\left[\mathrm{N}_{2} \mathrm{H}_{4}\right] / k_{3} \approx k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{IrH}_{2}\right]^{\circ} / k_{3} \tag{11}
\end{equation*}
$$

Equations 2 and 3

$$
\begin{align*}
& d\left[(\mathrm{PCP}) \mathrm{IrN}_{2} \mathrm{H}_{4}\right] / d t=k_{2} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{NH}\right]\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]-k_{3} \cdot\left[(\mathrm{PCP}) \mathrm{IrN}_{2} \mathrm{H}_{4}\right] \approx 0  \tag{12}\\
& {\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{NH}\right] \approx k_{3} \cdot\left[(\mathrm{PCP}) \operatorname{Ir} \mathrm{N}_{2} \mathrm{H}_{4}\right] /\left(k_{2}\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]\right)} \tag{13}
\end{align*}
$$

Substituting of Equation 11

$$
\begin{equation*}
\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{NH}\right] \approx k_{3} \cdot\left[k_{1} \cdot\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ} / k_{3}\right] /\left(k_{2} \cdot\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]\right) \approx k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{IrH}_{2}\right]^{\circ} /\left(k_{2} \cdot\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]\right) \tag{14}
\end{equation*}
$$

Consumption of hydrazine (Equations 4 and 6):

$$
\begin{align*}
& -d\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right] / d t=k_{2} \cdot\left[(\mathrm{PCP}) \operatorname{IrH}_{2} \mathrm{NH}\right] \cdot\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]+k_{4} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2}\right] \cdot\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]= \\
& \left.\quad k_{2} \cdot k_{1} \cdot[(\mathrm{PCP}) \operatorname{IrH}]_{2}\right]^{\circ} /\left(k_{2} \cdot\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]\right) \cdot\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]+k_{4} k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} /\left(k_{4} \cdot\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]\right) \cdot\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]= \\
& 2 \cdot k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \tag{15}
\end{align*}
$$

$\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]$

$$
\begin{equation*}
-\int d\left[\mathrm{~N}_{2} \mathrm{H}_{4}\right]=2 \cdot k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \cdot t \tag{16}
\end{equation*}
$$

$\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]_{\text {start }}$

$$
\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]=\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]_{\mathrm{start}}-2 \cdot k_{1} \cdot\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ} \cdot t=\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]^{\circ}-\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ}-2 \cdot k_{1} \cdot\left[(\mathrm{PCP}) \mathrm{IrH}_{2}\right]^{\circ} \cdot t(17)
$$

Hydrazine in a complex with $(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right),\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right) \mathrm{N}_{2} \mathrm{H}_{4}\right] \approx\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)_{2}\right]^{\circ}$.
The total amount of hydrazine, both free and bound

$$
\begin{equation*}
\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]+\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \approx\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]^{\circ}-2 \cdot k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \cdot t \tag{18}
\end{equation*}
$$

Formation of ammonia (Equations 3 and 4):

$$
\begin{align*}
d\left[\mathrm{NH}_{3}\right] / d t=k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)-\mathrm{N}_{2} \mathrm{H}_{4}\right]+k_{2} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)=\mathrm{NH}\right] \cdot\left[\mathrm{N}_{2} \mathrm{H}_{4}\right]= \\
k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ}+k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ}=2 \cdot k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \tag{19}
\end{align*}
$$

$\left[\mathrm{NH}_{3}\right]$

$$
\begin{equation*}
\int d\left[\mathrm{NH}_{3}\right]=\left[\mathrm{NH}_{3}\right]=2 \cdot k_{1} \cdot\left[(\mathrm{PCP}) \operatorname{Ir}\left(\mathrm{H}_{2}\right)\right]^{\circ} \cdot t \tag{20}
\end{equation*}
$$
